Time from planting to harvest is about 60 days, and you don't need a lot of tarragon. One plant supplies the average family, so if you're growing a lot you will be able to supply the whole neighborhood. Pick the tender top leaves of tarragon as you need them. Cut back the leafy top growth several times during the season to encourage the plant to bush out.

Tarragon

Tarragon seedling

storing and preserving

Tarragon is best fresh, but can be dried or frozen. Detailed information on storing and preserving is given in Part 3.

Serving suggestions

Put a fresh stem or two of tarragon into bottles of good cider vinegar or wine vinegar and, vo/7a, tarragon vinegar; allow a couple of weeks for the flavor to develop before you use it. Since the flavor of tarragon is so distinctive, use it with a light touch. Use the leaves to decorate cold dishes glazed with aspic. It's tarragon that gives a kick to a good *sauce tartare,* and, of course, you can't have chicken tarragon without it.

Thyme

Common name: thyme
Botanical name: Thymus vulgaris
Origin: Mediterranean

Varieties
Argentens; Aureus; Rosens; Broadleaf English; Narrowleaf French.

Description

Thyme is a fragrant, small, perennial evergreen shrub with six- to eight-inch stems that often spread out over the ground. It's a member of the mint family and has square stems with small opposite leaves and pale lavender mintlike flowers. Thyme is a charming, cheerful little plant and will last for years once it's established. It's a good plant for a border or rock garden. There a more than 200 species and man^ hybrids, but the common form i

Thyme

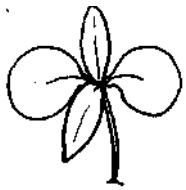
the one grown for flavoring. The Greeks and Romans believed that thyme gave courage and strength; their highest compliment was to tell a man that he smelled of thyme. In the Middle Ages ladies embroidered sprigs of thyme on the scarves they gave their knights. Linnaeus, the father of modern botany, recommended thyme as a hangover cure.

Where and when to grow

Thyme prefers a mild climate but can survive temperatures below freezing. It tolerates cold better in well-drained soil. Plant thyme from seed anywhere in the United States two to three weeks before your average date of last frost.

How to plant

Thyme likes well-drained soil, preferably low in fertility; rich soils produce plants that are large but less fragrant. The first year, work a low-nitrogen (5-10-10) fertilizer into the soil before planting at the rate of about a half pound per 100 square feet. This is generous of you, because in adverse soil conditions thyme, like many herbs, will have better flavor. Whatever the soil's like, it's important to give thyme a place in the sun. Plant seeds in early spring, two to three weeks before your average date of last



Thyme seedling

frost. Plant the seeds a quarter inch deep in rows 16 to 24 inches apart, and when the seedlings are two to three inches tall thin them about a foot apart. You can also plant thyme cuttings or root divisions. Plant them at the same time, and space them a foot apart.

Fertilizing and watering

Don't fertilize at midseason. Detailed information on fertilizing is given in "Spadework: The Essential Soil" in Parti.

Thyme seldom needs watering; it does best on the dry side.

Special handling

Some herbs, like mints, grow like weeds whatever the competition. Thyme can't handle competition, especially from grassy weeds, and needs an orderly environment; cultivate conscientiously.

Start new plants every three to four years, because thyme gets woody; reduce the clump greatly. If you've no room in the garden for extra plants, plant them in a hanging basket.

Pests

Thyme has no serious pest problems. Like most herbs, it's ideal for the organic gardener.

Diseases

Thyme has no serious disease problems.

When and how to harvest

Pick thyme as needed. For drying, harvest when the plants begin to bloom. Cut off the tops of the branches with four to five inches of flowering stems.

Storing and preserving

After drying, crumble the thyme and put into tightly capped jars. Detailed information on storing and preserving is given in Part 3.

Serving suggestions

Thyme is usually blended with other herbs and used in meat dishes, poultry, stuffings (parsley and thyme is a happy combination), and soups. It adds a nice flavor to clam chowder and is often used along with a bay leaf to give a delicate lift to a white sauce or a cheese souffle.

How to Store Vegetables

Once you've harvested your crops, you may find yourself with a big surplus. What do you do with all those vegetables? Well, you can — and will — enjoy them fresh; and you can also give a lot of them away. You can keep them in the refrigerator for a few days. You can freeze, can, or dry them for the months ahead, as detailed in the following chapters. But in some cases, cold storage — not freezing — can be your best bet. It's a low-effort, electricity-free choice that can keep you supplied with fresh vegetables all winter long. Both refrigerator storage and cold storage are discussed below, and the accompanying chart shows you which methods of storing or preserving work best for each vegetable.

SHORT-TERM REFRIGERATOR STORAGE

Most vegetables keep best for a short time when stored in the refrigerator, at a high humidity and a constant temperature, just above freezing. A temperature of about 40°F and a humidity of 95 percent are ideal for storing fresh vegetables, and these conditions are most likely to be found in the crisper or hydrator sections of the refrigerator. For the best results, the crisper should be at least two-thirds full; if it's empty or almost empty, vegetables placed in it will dry out.

To keep vegetables moist and fresh, follow these simple rules of refrigerator storage:

- Store vegetables in the crisper or hydrator, and keep the crisper full.
- When storing only a few vegetables, put them into airtight plastic bags or plastic containers, then into the crisper.
- When storing vegetables in other parts of the

refrigerator, put them into airtight plastic bags or plastic containers to prevent moisture loss.

Almost all vegetables store well in the refrigerator, but there are a few that don't. Mature onions, peanuts (dried), potatoes, sweet potatoes, pumpkins, winter squash, and such root vegetables as rutabagas, salsify, and turnips keep better in cold storage outside the refrigerator, in a basement storage room or root cellar. This type of storage is discussed in the next section. Most other vegetables, regardless of whether they *can* be kept in cold storage, keep very well for a short time in the refrigerator.

Preparing vegetables for refrigerator storage

Refrigerator storage is the simplest type of storage to prepare for — all you have to do is sort the vegetables, remove damaged or soft ones for immediate use or discard, and remove as much garden soil as you can. Some vegetables should be washed before they're stored; others keep better when they're not washe^d until you're ready to use them. The directions below tell you how to prepare each type of vegetable for refrigerator storage. For the best results, discard damaged vegetables or use them immediately; perfect vegetables keep best.

Artichokes

Do not wash until ready to use. Store in plastic bag up to 2 weeks.

Asparagus

Do not wash until ready to use. Slice off bottoms of stalks and stand upright in 1 to 2 inches of water. Store up to 1 week.

Beans, green or snap

Do not wash until ready to use. Store in plastic bag up to 1 week.

Beans, broad, dry, lima, or mung

Do not shell or wash until ready to use. Store in plastic bag up to 1 week.

Beets

Cut off tops, leaving about 1 inch of stem. Do not wash roots until ready to use. Store in plastic bag for 1 to 3 weeks. Wash greens thoroughly in cold water; drain well and store in plastic bag up to 1 week.

Broccoli

Do not wash until ready to use. Remove any damaged leaves. Store in plastic bag up to 1 week.

Brussels sprouts

Do not wash until ready to use. Remove any damaged leaves. Store in plastic bag up to 1 week.

Cabbage

Do not wash until ready to use. Remove any damaged leaves. Store in plastic bag for 1 to 2 weeks.

Cardoon

Trim roots and cut off leaves. Wash thoroughly in cold water; drain well. Store stalks attached to root in plastic bag for 1 to 2 weeks.

Carrots

Cut off tops. Wash thoroughly in cold water; drain well. Store in plastic bag for 1 to 3 weeks.

Cauliflower

Do not wash until ready to use. Remove any damaged leaves. Store in plastic bag up to 1 week.

Celeriac

Cut off leaves and root fibers. Do not wash until ready to use. Store in plastic bag up to 1 week.

Celery

Trim roots and wash thoroughly in cold water; drain well. Cut off leaves and store in plastic bag for 3 to 5 days. Store stalks attached at root in plastic bag fori to 2 weeks.

Chard

Wash thoroughly in cold water; drain well. Trim any bad spots on leaves and cut off tough stalks. Store in plastic bag for 1 to 2 weeks.

Chayote

Do not wash until ready to use. Store in plastic bag up to 1 week.

Chick peas

Do not shell or wash until ready to use. Store in plastic bag up to 1 week.

Chicory

Do not wash until ready to use. Store in plastic bag up to 1 week.

Chinese cabbage

Trim roots and wash thoroughly in cold waters- drain well. Store in plastic bag up to 1 week.

Collards

Wash thoroughly in cold water; drain well. Remove any damaged leaves. Store in plastic bag up to 1 week.

Corn

Do not husk or wash; store in plastic bag for 4 to 8 days. For best flavor, do not store; use immediately.

Cress, garden

Wash thoroughly in cold water; drain well. Store in plastic bag up to 1 week.

Cucumbers

Wash thoroughly in cold water and pat dry. Do not cut until ready to use. Store in plastic bag up to 1 week.

Dandelion

Cut off roots and remove any damaged leaves. Wash thoroughly in cold water; drain well. Store in plastic bag up to 1 week.

Eggplant

Store eggplant at about 50°F, up to 1 week. Do not refrigerate.

Endive

Wash thoroughly in cold water; drain well. Remove any damaged leaves. Store in plastic bag up to 1 week.

Fennel

Do not separate stalks or wash until ready to use. Store in plastic bag up to 1 week.

Horseradish

Cut off leaves and trim root; wash thoroughly in cold water and pat dry. Mix with vinegar and water according to recipe in "How to Freeze Vegetables." Store in airtight glass jar in refrigerator for i to 2 weeks. For stronger flavor, grate as soon as possible after picking; store in airtight glass jar.

Jerusalem artichokes

Wash tubers thoroughly in cold water and pat dry. Store in plastic bag for 7 to 10 days.

Kale

Wash thoroughly in cold water; drain well. Remove any damaged leaves. Store in plastic bag up to 1 week.

Kohlrabi

Cut off leaves and trim root; wash thoroughly in cold water and pat dry. Store in plastic bag up to 1 week.

Leeks

Cut off roots and all but 2 inches of leaves. Do not wash until ready to use. Store in plastic bag up to 1 week. Wash very thoroughly in cold water before using.

Lentils

Do not shell or wash until ready to use. Store in plastic bag up to 1 week.

Lettuce

Wash thoroughly in cold water; drain well. Store in plastic bag up to 2 weeks.

Mushrooms

Do not wash until ready to use. Store in open plastic bag or spread on a tray and cover with damp paper towels. Store up to 1 week. Wash quickly in cold water before using; pat dry.

Muskmelon

Do not wash. Store in plastic bag up to 1 week; cover cut surfaces with plastic wrap.

Mustard

Wash thoroughly in cold water; drain well. Remove any damaged leaves. Store in plastic bag up to 1 week.

Okra

Do not wash until ready to use. Store in plastic bag for 7 to 10 days.

Onions^ green

Wash thoroughly in cold water; drain well. Store in plastic bag up to 1 week. Do not refrigerate mature onions.

Parsnips

Cut off tops, leaving about 1 inch of stem. Do not wash until ready to use. Store in plastic bag for 1 to 3 weeks.

Peas, black-eyed

Do not shell or wash until ready to use. Store in plastic bag up to 1 week.

Peas, shelling

Do not shell or wash until ready to use. Store in plastic bag up to 1 week. For best flavor, do not store; use immediately.

Peppers

Do not wash until ready to use. Store in plastic bag up to 1 week.

Radishes

Cut off tops. Do not wash until ready to use. Store in plastic bag 1 to 2 weeks.

Rhubarb

Cut off leaves. Wash stalks thoroughly in cold water; drain well. Store in plastic bag up to 2 weeks.

Salsify

Cut off tops, leaving about 1 inch of stem. Do not wash roots until ready to use. Store in plastic bag for 1 to 3 weeks.

Shallots

Wash thoroughly in cold water; drain well. Store in plastic bag up to 1 week.

Sorrel

Wash thoroughly in cold water; drain well. Remove any damaged leaves. Store leaves or stalks in plastic bag fori to 2 weeks.

Soybeans

Do not shell or wash until ready to use. Store in plastic bag up to 1 week.

Spinach, New Zealand spinach

Trim roots and tough stalks. Wash very thoroughly in cold water; drain well. Store in plastic bag up to 1 week.

Sprouts (sprouted vegetable seed, any type)

Store in plastic bag up to 1 week. Use sprouts **as** soon as possible.

Squash, summer

Do not wash until ready to use. Store in plastic bag up to 1 week.

Tomatoes

Wash thoroughly in cold water; pat dry. Store uncovered up to 1 week, depending on ripeness. Let green tomatoes ripen at room temperature, out of direct sun or in cold storage; then store as above.

Turnips

Cut off tops, leaving about 1 inch of stem on roots. Do not wash roots until ready to use. Store in plastic * bag for 1 to 3 weeks. Wash greens thoroughly in cold water; drain well. Store in plastic bag for up to 1 week. Do not refrigerate turnip roots; keep in cold storage.

Watermelon

Wash thoroughly in cold water; pat dry. Store uncovered up to 1 week; cover cut surfaces with plastic wrap.

COLD STORAGE: KEEPING VEGETABLES FRESH ALL WINTER

Cold storage is an old-fashioned but time-tested method for keeping raw, whole vegetables through the winter. If you've planted a big vegetable garden and if you've got (or can construct) the storage space, storing can be the most practical way to go.

You'll find many vegetables from your garden well-suited to cold storage, including beets, carrots, onions, parsnips, potatoes, pumpkins, sweet potatoes, turnips, winter squash, and many others. For a complete list, see "Directions for storing vegetables," later in this chapter. Other vegetables should be used fresh or preserved. Vegetables that are not suitable for cold storage include asparagus, fresh shelling beans, green beans, chayote, corn, cucumbers, eggplant, fresh greens — beet greens, chard, cress, dandelion, endive, lettuce, mustard, and sorrel — fresh lentils, mushrooms, okra, green onions, fresh peas and chick peas, fresh peanuts, new potatoes, radishes, rhubarb, fresh soybeans, spinach and New Zealand spinach, summer squash, and ripe tomatoes. Shelled dried beans, lentils, peas and chick peas, soybeans, and dried peanuts can be kept up to one year in cold storage.

Late-ripening and maturing vegetables are the best choices for cold storage. Certain varieties take better to this method than others — late cabbage, for example. Check seed catalogs and packets before you buy and plant, and talk to the specialists at your County or State Extension Service Office. They can help you decide what vegetables to plant when you're planning your garden, and what storage methods work best in your area.

How cold storage works

Like any other method of food preservation, cold storage keeps food from decomposing by stopping or slowing down the activity of enzymes, bacteria, yeasts, and microbes that can eventually spoil food. In cold storage, this is done by keeping fresh, raw, whole vegetables at temperatures between 32°F and 40°F. In this range, the food won't freeze, but it stays cold enough to stop the spoilers. The length of storage time varies with each vegetable, from a few weeks for broccoli or cauliflower to four to six months for potatoes. Dried beans and peas will keep the longest — 10 to 12 months.

One of the advantages of storing your vegetables is that you don't risk eating unwholesome, spoiled food. If the food goes bad, you can tell almost immediately by the way it looks, smells, or feels. But there's still a lot to learn about storage. For example, squash have to be kept warmer than do carrots, so these two vegetables can't be stored In the same spot. Or, if you plan to keep cabbages or turnips, don't store them indoors in the basement; you'll soon find their strong, distinctive odor penetrating up into the house. And, if you live in a climate where heavy snow is common in winter, outdoor storage of vegetables in mounds or barrels isn't going to be practical for you, because deep snow will make them inaccessible In winter.

Although storing vegetables may sound easy, it's a lot more complex than at first meets the eye. Although you don't have to do any chopping, blanching, or processing of vegetables to be stored, each vegetable does have to be handled in a special manner. Perhaps the trickiest part of all is that you've got to keep a weather eye on your stored food. Since the temperature of cold storage depends on the temperature outdoors, you may sometimes have to move or change the location of stored vegetables, open windows or vents, or adjust the humidity level. When storing food indoors, keep a thermometer as well as a humidity gauge in the storage area so you can accurately monitor temperature and moisture conditions.

Because it's harder to control the temperature of stored food, spoilage can happen more easily than with any other form of food preservation. Routine checks for spoilage will help you prevent food losses when storing vegetables indoors — but, once you open up an outdoor mound or barrel, you'll have to empty it of all the stored vegetables at once.

Storage methods for vegetables

Before the days of refrigerators, freezers, and supermarkets, most families depended on cold storage to keep a supply of vegetables all year long. In colonial times, a certain portion of every harvest was kept in cool caves or in straw-lined pits that could withstand freezing temperatures. In later times, most houses were built to include root cellars or cold, damp basements intended as storage areas. These chilly spots were perfect for keeping root vegetables, celery, pumpkin, squash, potatoes, arid other vegetables through the cold months.

Compared to houses of a century ago, our modern dwellings are snug, warm, and dry. Today, very few homes offer the cool, damp basement corners, outdoor sheds, or attics that formerly served as food storage areas. That means you'll have to plan, and perhaps construct, one or more special spots for cold storage of your garden's bounty — particularly if you plan to store a variety of vegetables.

In milder climates, where frost is infrequent and doesn't penetrate too deeply, vegetables can be kept in specially prepared outdoor locations. In colder areas, you'll have to store the vegetables indoors as an extra precaution against freezing. In the directions for storing vegetables that follow, you'll find the proper storage method for each vegetable.

Four vegetable groups

Where and how you store each vegetable will depend on how much or how little cold it can take and the amount of humidity it needs to keep fresh. Vegetables to be stored fall into four groups: cold-moist, cool-moist, cold-dry, and cool-dry.

Vegetables that should be cold-moist stored make up the largest group, and include beets, broccoli, Brussels sprouts, cabbage, carrots, cauliflower, celery, turnips, and many others. These vegetables require the coldest storage temperatures — 32°F — and the highest humidity — 95 percent — of all vegetables that can be stored.

The second group of vegetables requires cool-moist: melons, peppers, potatoes, and green tomatoes. These vegetables can be kept at temperatures ranging from 38°F to 60°F and at humidity levels of 80 to 90 percent.

Dry onions and shallots require cold-dry storage temperatures of 32°F to 35°F and humidity of 60 to 75 percent.

The cool-dry group is composed of pumpkin and winter squash, dried peas and beans, and live seeds, all of which must be stored at temperatures of 50°F to 55"F and at a humidity of 60 to 70 percent.

Vegetables in the cold-moist and cool-moist groups can be stored outdoors in a mound or barrel, or indoors in a specially insulated basement storage room that is partitioned off from the central heating area or a root cellar. Vegetables in the cold-dry and cool-dry groups can be stored indoors in a cool area of a heated basement, but they must be kept away from water that might condense and drip down from overhead pipes. Cold-dry storage can also be provided by a dry shed or attic, window wells, or cellar stair storage.

The accompanying chart shows how vegetables in each of these four groups should be stored — at what temperature, at what humidity, and for how long. Any one of the storage methods discussed in this chapter can be used if it supplies the necessary conditions of temperature and humidity. For some vegetables in the cool-moist group, the refrigerator is an ideal storage area. And when cold storage doesn't add significantly to the length of time you can keep a vegetable from the cold-moist group, you may prefer just to refrigerate your crop, as detailed above.

Recommended storage conditions

Vegetable	Temperature	Humidity	Storage Period
Cold-moist group:			
Artichokes	32°-34°F	90-95%	1 month
Beets (roots only)	32°-34°F	90-95%	5-6 months
Broccoli	32°-34°F	90-95%	2-3 weeks
Brussels sprouts	32°-34°F	90-95%	1 month
Cabbage	32°-34°F	90-95%	3-4 months
Cardoon	32°-34°F	90-95%	2-3 months
Carrots	32°-34°F	90-95%	4-5 months
Cauliflower	32°-34°F	90-95%	2-3 weeks
Celeriac	32°-34°F	90-95%	2-3 months
Celery	32°-34°F	90-95%	2-3 months
Chicory			
roots and greens	32°-34°F	85-90%	2-3 months
roots only	32°-34°F	90-95%	10-12 months

Recommended storage conditions continued

Vegetable	Temperature	Humidity	Storage Period
Chinese cabbage	32°-34°F	90-95%	2-3 months
Collards	32°-34°F	90-95%	2-3 weeks
Fennel	32°-34°F	90-95%	2-3 months
Horseradish	32°-34°F	90-95%	10-12 months
Jerusalem artichokes	32°-34°F	90-95%	2-5 months
Kale	32°-34°F	90-95%	2-3 weeks
Kohlrabi	32°-34°F	90-95%	1-2 months
Leeks	32°-34°F	90-95%	2-3 months
Parsnips	32°-34°F	90-95%	2-6 months
Rutabagas	32°-34°F	90-95%	2-4 months
Salsify	32°-34°F	90-95%	2-4 months
Turnips			
roots	32°-34°F	90-95%	4-5 months
greens	32°-34°F	90-95%	2-3 weeks
Cool-moist group:			
Muskmelons	45°-50°F	85-90%	2-3 weeks
Peppers, sweet or hot	45°-50°F	85-95%	2-3 weeks
Potatoes	38°-40°F	85-90%	4-6 months
Sweet potatoes	55°-60°F	85-90%	4-6 months
Tomatoes, green	55°-60°F	85-90%	1 month
Watermelons	45°-55°F	80-85%	2-3 weeks
Cold-dry group:			
Onions (mature)	32°-34°F	60-75%	6-7 months
Seed, live	32°-40°F	65-70%	10-12 months
Shallots	32°-34°F	60-75%	2-8 months
Cool-dry group:			
Beans, dried (broad, dry, horticultural, or lima)	32°-50°F	65-70%	10-12 months
Chick peas, dried	32°-50°F	65-70%	10-12 months
Lentils, dried	32°-50°F	65-70%	10-12 months
Peas, dried (shelling, black-eyed)	32°-50°F	65-70%	10-12 months
Peanuts, dried	32°-50°F	65-70%	10-12 months
Pumpkins	50°-55°F	60-75%	3-6 months
Soybeans, dried	32°-50°F	65-70%	10-12 months
Squash, winter	50°-60°F	70-75%	5-6 months

OUTSIDE STORAGE

Where winters are mild and there isn't much snow, outside storage is an easy answer to holding large crops. You can store vegetables in well-insulated mounds or barrels, or in little underground lean-tos. Both cold-moist and cool-moist vegetables can be stored in these outdoor locations.

Mound storage

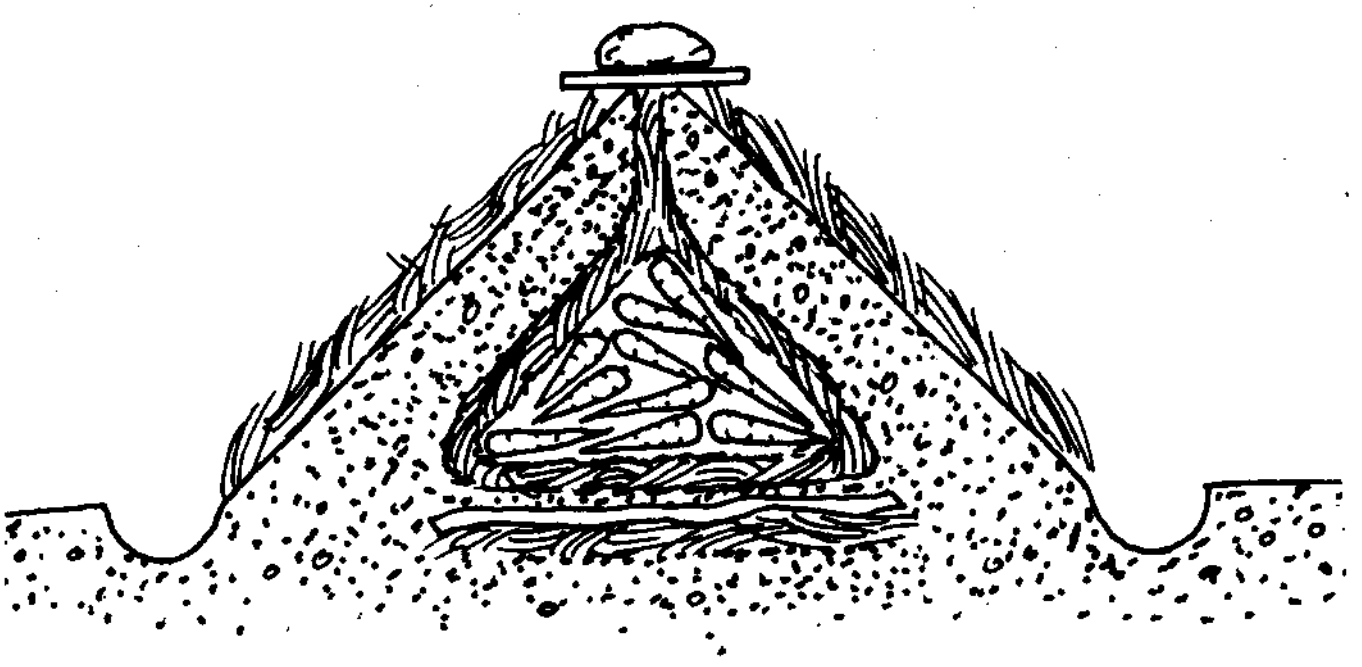
When planning mound storage, first find a spot in your garden where the mound will have good drainage. Dig a shallow, dish-shaped hole six to eight inches deep, and line it with straw or leaves. Spread the straw bed with some metal screening (to keep 6ut burrowing animals), and then stack your vegetables in a cone on the prepared bed. Wrap the individual pieces and separate the layers of food with packing material.

Making a cone or volcano shape, cover the mound with more straw or leaves, then shovel on three or four inches of dirt. Cover all but the top of the cone. Pack the dirt firmly with the back of your shovel. Pile on another thick (six- to eight-inch) layer of straw, but don't cover the top of the cone — it must be left open for ventilation. Put a piece of board on top of each mound to protect it from the weather. If necessary, weight the board with a stone or a brick to keep it in place. Finally, dig a shallow drainage ditch around the mound.

You can store several kinds of vegetables in the same mound, if they're separated by packing material — that way you can enjoy a bushel of mixed vegetables instead of all carrots or all potatoes. However, several small mounds are more practical than one large mound. Once you've opened a mound, it can't be repacked again—which means you'd have to take out all the vegetables at one time. With several smaller mounds, you can bring manageable portions of vegetables into the house, without having to disturb the whole store. The U.S. Department of Agriculture recommends changing the location of the pits every year to avoid contamination.

Cabbage mound storage

If you want to be able to remove cabbages a few at a time, you can store heads in a mound that's rectangular rather than volcano-shaped. Prepare a long, narrow, rectangular mound with the same base of straw or leaves, metal screening, and more straw, as directed for mound storage. Then put in the individual heads of cabbage head-down in one layer, more straw, and a final layer of dirt. Dig a small trench along each long side of the mound to drain off water. With this type of mound, you can remove just a few cabbages at a time, because there's only one layer of heads.



A storage mound in a garden provides safe keeping for your vegetables. A ground-level screen discourages burrowing animals; layers of straw and dirt topped by a board shelter the vegetables inside the cone-shaped mound.

Barrel storage

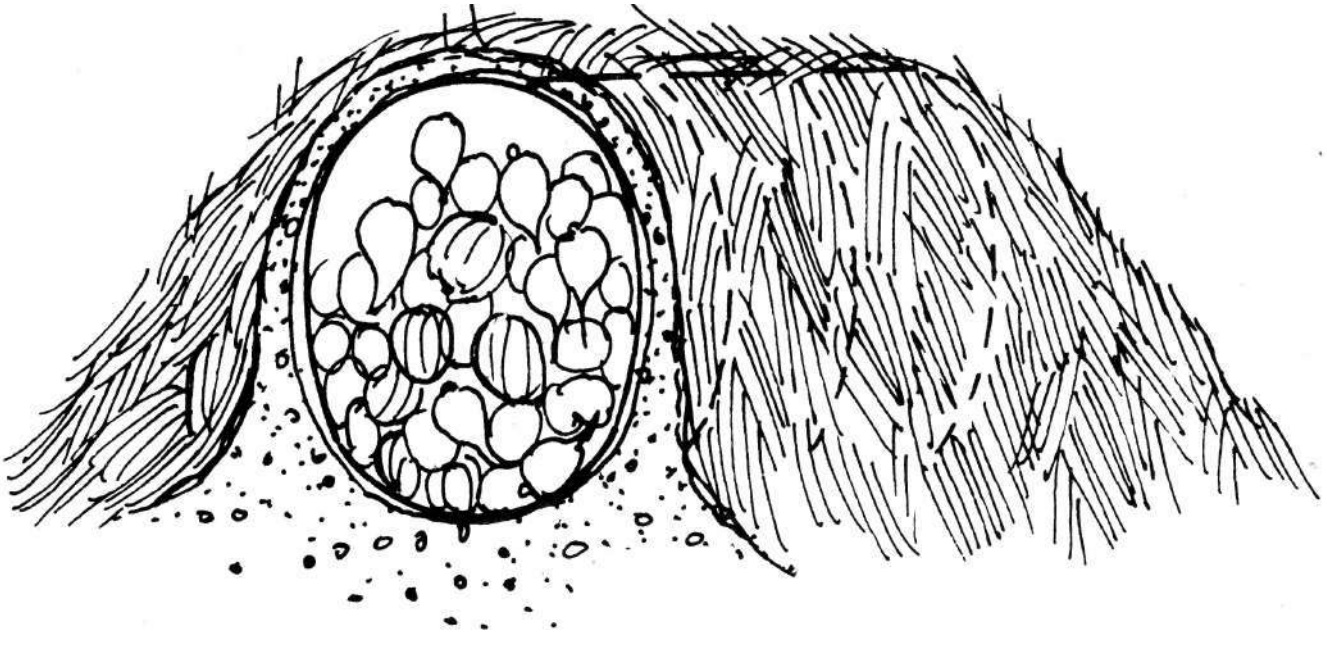
Choose a well-drained spot in your garden for barrel storage. Dig out a hole deep enough to cradle the barrel on its side — the barrel doesn't have to be completely buried. Line the hole with straw, and nest the barrel into it. Pack in the vegetables, cover the barrel opening with metal screening or tight-fitting wood covers to keep out rodents, then cover the whole barrel with several insulating layers of straw and dirt. Be sure to mark the location of the barrel mouth, so you can find it easily when you're ready to dig out the vegetables.

Frame storage

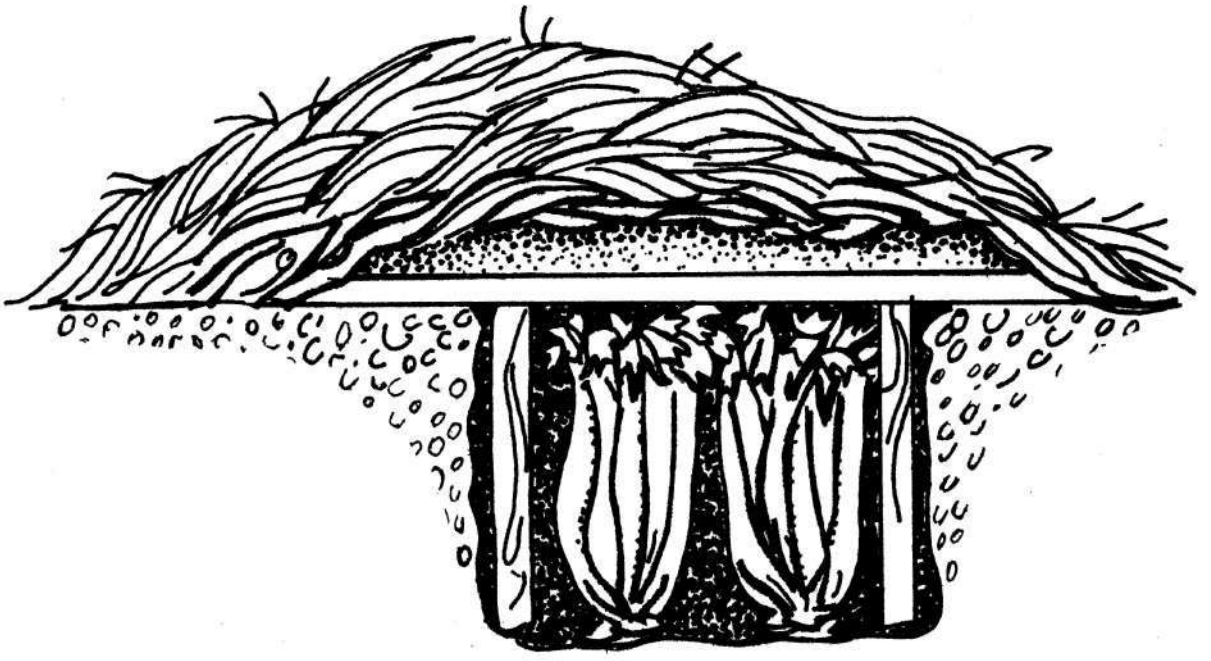
Frame storage is a special method that works best for celery and celerylike vegetables, such as Chinese cabbage and fennel. In this little underground lean-to, you store the celery bunches upright with their roots in the ground. Dig a trench about one foot deep, two feet wide, and as long as needed to hold the celery you've grown. Harvest the celery, leaving the roots intact, and stand the bunches up — closely together— in the trench. Water the roots, and leave the trench open until the celery tops are dry. Build a lean-to over the celery with the boards — set a wide board on edge along one side of the trenched celery, and prop another wide board against this support to make a slanted roof over the bunches of celery. Finally, cover the lean-to with straw and then with dirt.

INDOOR STORAGE — THE ROOT CELLAR

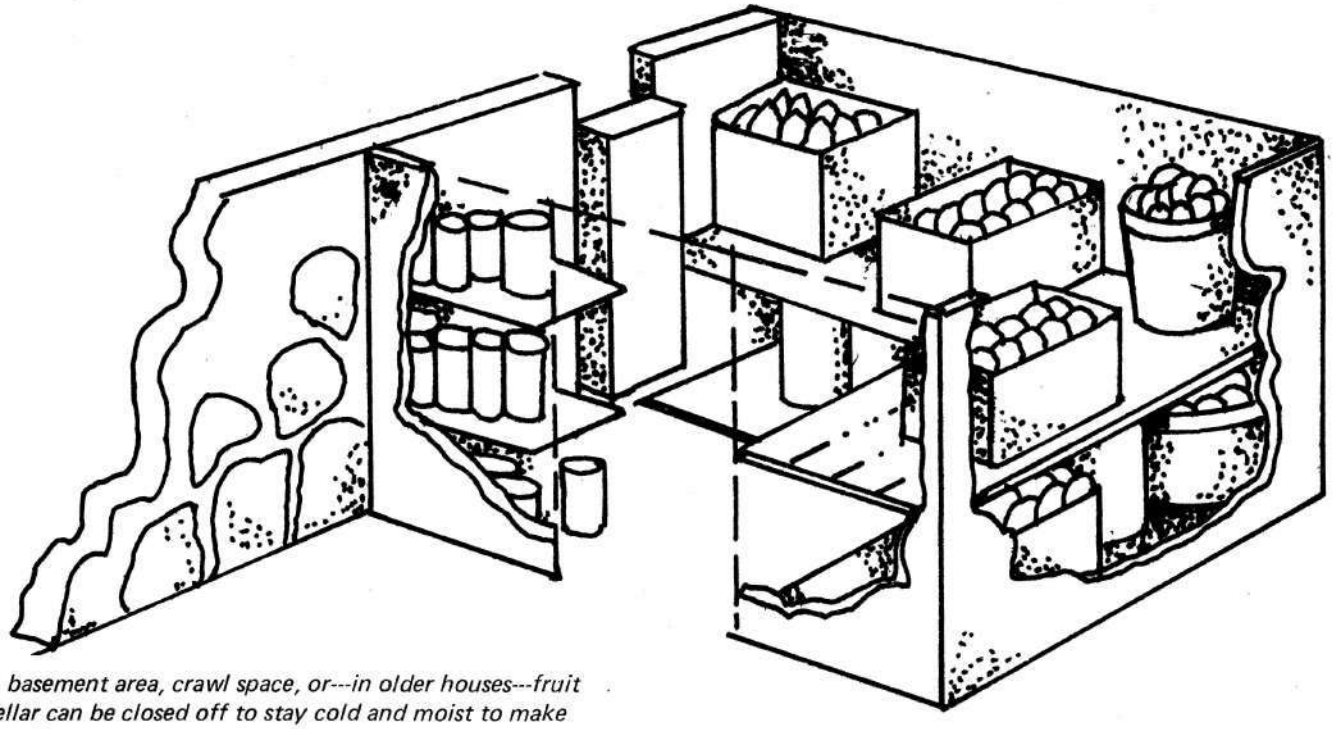
If you live in a region where freezing or very snowy weather is common in winter, you'll need to store your vegetables indoors. Your house (or possibly another building on your property) may offer several of the storage areas described in this section, or you may decide to build a basement cold storage room. If you live in an older house, there may be a fruit cellar or cold corner that could easily be closed off to stay cold and moist. Or, your newer house may have a crawl space that's cold and damp. However it's done, indoor storage calls for a bit more upkeep than outdoor storage, since you've got to keep an eye on the temperature, the ventilation, and the humidity to which your vegetables are exposed, as well as make routine checks for spoilage.



An alternative to the traditional mound method of storage is a barrel placed on its side and set in a well-drained outdoor location. Screens or wood over the opening keep out animal intruders; straw and dirt provide insulation.



Vegetables like celery, Chinese cabbage, or lettuce store well in frames. To make a frame, stand the vegetables in bundles in a trench about one foot deep. Cover them with a lean-to of boards and mound straw and dirt over the top.



A basement area, crawl space, or---in older houses---fruit cellar can be closed off to stay cold and moist to make an effective root cellar for your vegetables. Many vegetables can be stored all winter in a well-planned root cellar.

Check around your property to see if it offers storage areas like those described in this section. Test the temperature and humidity in any area you're considering *before* you use it for storing your vegetables. The ideal time to plan your storage area is in winter before you plant.

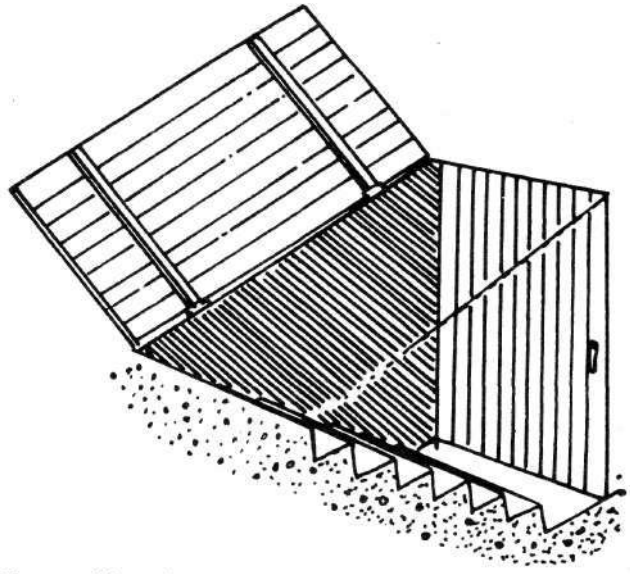
Temperature. You'll need to put up a reliable indoor/outdoor thermometer in your storage area. Most vegetables are stored at temperatures below 40°F but above freezing. However, there are some exceptions; watery vegetables such as tomatoes, green peppers, winter squash, and pumpkins, must all be cool-stored at temperatures above 40°F to keep from spoiling.

Humidity. Unless extra humidity is provided, your cold-moist and cool-moist stored vegetables will dry up and shrivel when stored indoors. Keep a humidity gauge in your storage area to be sure the vegetables are getting neither too much nor too little humidity, and make any necessary adjustments from time to time. You don't need fancy equipment or techniques for maintaining the right humidity. You might put pans of water or a tub of dampened sand on the floor; cover the floor with damp straw, sand, or sawdust; use damp sand or sawdust for packing the food; or line packing boxes with plastic bags.

Ventilation. You need ventilation in your storage area in case the indoor temperature grows too warm for the vegetables you're keeping. If that should happen, you must let in some cold winter air to cool things off. Good ventilation can be provided by a vent to the outside, a window, or a door. Although it's simple enough to open a window or a door to lower the temperature of your storage place, you must also protect your stored vegetables from contact with the air. Oxygen reacts with other substances in food to cause changes that will spoil the food. Since whole vegetables "breathe," they must be wrapped or packed in materials that will prevent oxidation. You must also keep the vegetables separate from one another so any spoilage won't be able to spread. To do this, layer the vegetables with clean, dry leaves, sand, moss, or dirt, or wrap each vegetable individually in paper.

Cellar steps storage

If your house has an outside basement entrance with stairs going down, you can use it as a storage area — the stairs become your shelves. You'll need a door at the top of the stairs, and probably another door at the bottom of the stairs, over the existing house door, to hold in the basement's heat. Which door you use as access depends on the climate. In a



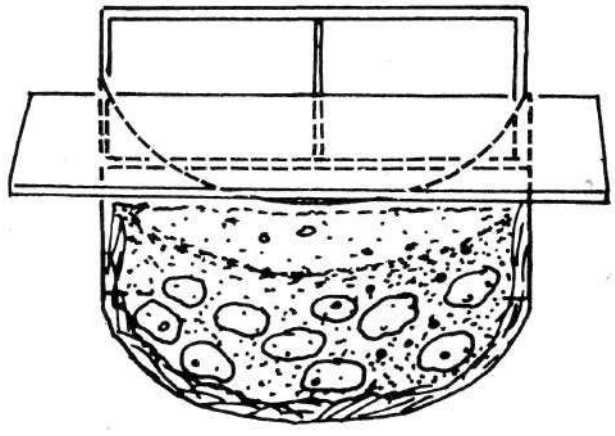
The outside stairs to your basement can make a good vegetable storage area. Set a plank on each step for insulation and check the temperature on each step.

vegetables. In colder climates, you may need to go through the basement. Cover the outside door to keep your vegetables from freezing.

Use a thermometer to check the temperature on each step and put barrels or boxes of food where the temperature is right for each item. It's a good idea to set a wooden plank as insulation on each step. If you need to add more humidity, set a bucket of damp sand on one of the steps.

Window well storage

Window wells can make nifty little storage areas, if they don't collect and hold water. Line the wells with



Line dry window wells with straw or bedding, put in the vegetables, then cover with a board or more bedding.

straw or bedding, put in the vegetables and add packing material, if necessary. Then cover the wells with boards or more bedding. If the windows open inward, you may be able to take vegetables out from the basement, without ever having to go outside and dig!

Dry shed or attic storage

Dry shed or attic storage provides cold, dry storage — just right for onions, shallots, pumpkins, and winter squash. By "dry shed," we mean any location that offers constant low temperatures and low humidity. This could be a garage, an unheated breezeway, a shed or storage building, even an unused doghouse, (if your garage or storage shed is fragrant with oil and gasoline, it's no good for storing vegetables. Some vegetables will absorb the oil and gasoline fumes and odors.) In milder winter zones, shelves in a storage shed or boxes on the floor may work well. If you live in a very cold region, you may have to insulate the corner of the shed to keep the vegetables from freezing.

Attic storage is convenient *only* if temperatures can be held somewhat constant. Since many attics will warm up quickly on a sunny day, you'll have to construct a special little storage area In it. Choose a spot that's well-insulated and near ventilation in the coldest part of the attic. Partition and roof it off from the rest of the attic, and use it for storing winter squash and onions.

Basement storage room

You can go all out and build a cold storage room in your basement. What you'll be doing is creating a separate little room, insulated from heat. You can get plans for constructing indoor cold storage rooms from agricultural extension offices, lumberyards, or gardening magazines.

Basically, you'll have to partition off an area that has no heating pipes or ducts. For ventilation, there should be a window — two or more windows if the room is partitioned. For air circulation, plan to have removable slatted flooring and shelves. Slatted flooring makes it easier to use dampened sawdust or other wet material to raise the humidity.

BASIC EQUIPMENT FOR STORING VEGETABLES

In addition to the proper indoor or outdoor storage areas, you'll need the following equipment to store your vegetables:

- Containers, such as wooden boxes, crates, barrels, or plastic garbage bags — cardboard boxes are only suitable for storing vegetables that need dry conditions.
- Newspapers or other paper for wrapping vegetables.
- Packing and insulating materials, such as sand, sawdust, peat, sphagnum moss, leaves, straw, or wood shavings.
- An indoor/outdoor thermometer for monitoring temperatures in an indoor storage area.
- A humidity gauge for monitoring the humidity in an indoor storage area.
- Metal screening for use as protection against contamination by rodents in outdoor storage areas.
- Wood slats for constructing lean-to and frames.
- A shovel for digging out mound, frame, or barrel storage areas.

BASIC COLD-STORING TECHNIQUES

Your vegetables must be harvested at just the right moment so they'll take well to storing and won't decay before you're ready to use them. Damaged or imperfect vegetables will spoil quickly, so you must be very careful when handling them prior to storing. Never store bruised or damaged vegetables; they can cause spoilage of your whole crop. It's usually better to clean off but not wash vegetables before storing, because washing can lead to the development of soft rot.

With methods of food preservation, you can process the food and then forget about it until you're ready to use it. Not so with storage. Since the temperature outdoors is the major factor affecting the. storage of your vegetables, you have to be constantly alert to the changes in weather. If it turns suddenly colder, warmer, or wetter, you must make whatever adjustments are needed to maintain the proper conditions in your storage area. You must also make regular spoilage checks of the boxes, bags, or bins of vegetables stored indoors.

Handling

Harvest vegetables as late as possible. For many vegetables, this means plant later than usual in order to get a late harvest. You should wait until the first frost warnings to harvest. Carrots, parsnips, potatoes, and turnips, for example, can stay in the ground even after the first frost or two, if the ground is well mulched.

Pick only perfect vegetables for cold storage and handle them carefully to avoid bruising. One bad item can spread decay to others and ruin the whole box, barrel, or mound.

Harvest on a dry day, if possible, and let the vegetables dry on the ground, in the sun, for several hours before packing them away. Onions often need several days of drying; potatoes, however, shouldn't be exposed to hot sun or strong wind. Produce should be cool when packed.

Wash vegetables, if you must, but most experts agree that all you really need to do is brush off excess dirt. The vegetables should be dry before you pack them.

Curing

Potatoes, pumpkins, and most types of winter squash have to be cured before storing. Curing is holding the vegetables at a warm temperature — 70°F to 85°F — in a dark, humid place for about 10 days. Curing hardens the skins and rinds and helps heal surface cuts, reducing mold and rot damage.

Packing

Some vegetables — potatoes, onions, and squash — can go from the garden right into boxes, barrels, plastic bags, or other containers. Root vegetables — such as beets, carrots, turnips, and parsnips — are better packed in some material such as newspaper that will insulate them, slow down their breathing, and keep them from touching one another, so decay can't spread from root to root.

You can wrap the vegetables separately in newspaper, then pack them loosely in boxes, barrels, or plastic bags. If you use plastic bags, poke a few holes in the bags to allow some ventilation. Other packing materials include damp or dry sand, sawdust, peat, sphagnum moss, leaves, straw, or wood shavings. Line the container with a layer of packing wood material, then arrange a layer of vegetables, leave space around each vegetable for packing material. Fill in around each vegetable and then again on top with a layer of packing material. Repeat these steps until the container is full. Be careful to leave enough room for examining the produce at the bottom of the container when you're making routine spoilage checks.

Moist sand is sometimes suggested for packing certain vegetables. You'll know the sand is just the right consistency if it feels cold and falls apart in your hand when squeezed, leaving just a few particles sticking to your skin.

DIRECTIONS FOR COLD-STORING VEGETABLES

If you plan to store a variety of vegetables, you'll probably have to arrange several different kinds of storage. The following directions for storing vegetables tell you which methods are best suited to each vegetable. Choose the one that works best for your climate and your available space.

Artichokes

Cut the fleshy, tight buds before they open. Artichokes are best stored in the refrigerator, but they can be kept in cold storage. Store on shelves or loosely packed in open boxes at 32°F to 34°F and 90 to 95 percent humidity (moist), with some air circulation. Store in a basement storage room or root cellar up to 1 month.

Beans, dried (broad, dry, or lima)

Dried beans won't freeze, and will store well when properly dried and packaged. Dry them according to the instructions in "How to Dry Vegetables." Then store them at 32°F to 50°F and 65 to 70 percent humidity (dry), with some air circulation. Store in a dry shed or attic for 10 to 12 months.

Beets

Choose late-maturing varieties and leave them in the ground until after the first few frosts. Dig them up when the soil is dry, and leave them on the ground for 3 or 4 hours. Remove the tops, leaving about 1/2 inch of the crowns. Don't remove the roots. Pack in packing material in wooden boxes, barrels, plastic bags with air holes, or in a mound or buried barrel. Store at 32°F to 34°F and 90 to 95 percent humidity (moist), with just a little air circulation. Beets will freeze at 30°F. Store in a basement storage room, root cellar, mound, or buried barrel for 5 to 6 months.

Broccoli

Harvest in late fall. Remove the root, but leave the leaves on as protection. Pack in boxes; separate and cover the stalks with moist sand. Store at 32°F to 34°F and 90 to 95 percent humidity (moist), with some air circulation. Broccoli will freeze at about 30°F. Store in a basement storage room or root cellar up to 3 weeks.

Brussels sprouts

Leave Brussels sprouts in the ground and mulch them heavily to protect the sprouts. Brussels sprouts plants can be stored in a frame, like celery, or in a mound, like cabbage, but often the size of the plants makes this impractical. Store Brussels sprouts

plants at 32°F to 34°F and 90 to 95 percent humidity (moist), with just a little air circulation. Store in a basement storage room or root cellar up to 1 month.

Cabbage

Choose late-maturing varieties. For storage in a root cellar, remove the roots, then cover the heads in moist dirt or sand in a bin. For outdoor mound storage, don't remove the stem or root. Place the cabbages head-down, pack straw between the heads, then cover with a final layer of dirt. Store at 32°F to 34°F and 90 to 95 percent humidity (moist), with just a little air circulation. Cabbage will freeze at 30°F. Store in a mound, buried barrel, or root cellar for 3 to 4 months. Do *not* store cabbages in a basement storage room; their strong odor can escape up into the house.

Cardoon

Harvest the plants with roots intact. Don't remove the tops. Set the roots firmly in moist sand or dirt so the plants stand upright, and construct a frame over the plants, as detailed earlier in this chapter. Keep the roots moist during storage, but don't water the leaves of the plants. Store at 32°F to 34°F and 90 to 95 percent humidity (moist), with just a little air circulation. Cardoon will freeze at just under 32°F. Store in a basement storage room, outside frame, or root cellar for 2 to 3 months.

Carrots

Choose late-maturing varieties, and leave them in the ground until after the first couple of frosts. After harvesting, leave them on the ground for 3 to 4 hours. Remove the tops, leaving about 1/2 inch of the crown. Don't remove the roots. Pack in packing material in wooden boxes, barrels, plastic bags with air holes, or bury in a mound. Store at 32°F to 34°F and 90 to 95 percent humidity (moist), with just a little air circulation. Carrots will freeze at about 30°F. Store in a basement storage room, mound, buried barrel, or root cellar 4 to 5 months.

Cauliflower

Harvest in late fall. Remove the root, but leave on the outer leaves as protection. Pack in boxes; separate and cover the heads with moist sand. Store at 32°F to 34°F and 90 to 95 percent humidity (moist), with a little air circulation. Cauliflower will freeze at about 30°F. Store in a basement storage room or root cellar for 2 to 3 weeks.

Celeriac

Dig up the roots when the soil is dry, and leave them on the ground for 3 or 4 hours. Cut off the tops, leaving 2 or 3 inches of the crown; don't remove the root fibers. Pack in wooden boxes, barrels, or plastic bags with air holes, or in a mound or buried barrel. Store at 32°F to 34°F and 90 to 95 percent humidity (moist), with just a little air circulation. Celeriac will freeze at just under 32°F. Store in a basement storage room, buried barrel,mound,or root cellar for 2 to 3 months.

Celery

Harvest the plants with roots intact. Don't remove the tops. Set the roots firmly in moist sand or dirt so the celery stands upright, and construct a frame over the plants, as detailed earlier in this chapter. Keep the roots moist during storage, but don't water the leaves of the plants. Store at 32°F to 34°F and 90 to 95 percent humidity (moist), with just a little air circulation. Celery will freeze at just under 32°F. Store in a basement storage room, outside frame, or root cellar for 2 to 3 months.

Chick peas^ dried

Dried chick peas won't freeze, and will store well when properly dried and packaged. Dry them according to the instructions in "How to Dry Vegetables." Then store them at 32°F to 50°F and 65 to 70 percent humidity (dry), with some air circulation. Store in a dry shed or attic for 10 to 12 months.

Chicory

Harvest the plants with the roots intact, and don't trim the leaves. Tie all the leaves together, then stand the plants upright in moist sand or dirt and construct a frame over the plants, as detailed earlier in this chapter. Store at 32°F to 34°F and 85 to 90 percent humidity (moderately moist), with just a little air circulation. Chicory will freeze at just under 32°F. Store in a basement storage room, outside frame, or root cellar for 2 to 3 months.

To store the roots only, dig them up when the soil is dry, and leave them on the ground for 3 to 4 hours. Remove the tops, leaving about 1/2 inch of the crowns. Pack in packing material in wooden boxes, barrels, plastic bags with air holes, or in a mound or buried barrel. Store at 32°F to 34°F and 90 to 95 percent humidity (moist), with just a little air circulation. Chicory roots freeze at about 30°F. Store in a basement storage room, mound, buried barrel, or root cellar for 10 to 12 months.

Chinese cabbage

Harvest the plant with roots intact. Don't remove the tops. Set the roots firmly in moist dirt so the cabbage stands upright and construct a frame over the plants, as detailed earlier in this chapter. Keep roots moist during storage but don't water the leaves of the plants. Store at 32°F to 34°F and 90 to 95 percent humidity (moist), with just a little air circulation. Chinese cabbage will freeze at just under 32°F. Store in a basement storage room, outside frame, or root cellar for 2 to 3 months.

Fennel

Harvest the plants with roots intact. Don't remove the tops. Set the roots firmly in moist sand or dirt so the plants stand upright, and construct a frame over the plants, as detailed earlier in this chapter. Keep the roots moist during storage, but don't water the leaves of the plants. Store at 32°F to 34°F and 90 to 95 percent humidity (moist), with just a little air circulation. Fennel will freeze at just under 32°F. Store in a basement storage room, outside frame, or root cellar for 2 to 3 months.

Horseradish

Choose late-maturing plants and leave them In the ground until after the first few frosts. Dig them up when the soil is dry, and leave them on the ground for 3 or 4 hours. Remove tops, leaving about 1/2 inch of the crown. Don't remove the roots. Pack in packing material in wooden boxes, barrels, plastic bags with air holes, or in a mound or buried barrel. Store at 32°F to 34°F and 90 to 95 percent humidity (moist), with a little air circulation. Horseradish freezes at about 30°F. Store in a basement storage room, mound, buried barrel, or root cellar for 10 to 12 months.

Greens (collards kale and turnip)

Harvest the plant with roots intact. Don't remove the tops. Set the roots firmly in moist dirt so it stands upright. Keep the roots moist during storage, but don't water the leaves of the plant. Store at 32"F to 34°F and 90 to 95 percent humidity (moist), with some air circulation. Greens freeze at just below 32°F. Store in a frame for 2 to 3 weeks.

jerusalem artichokes

Dig the roots when the soil is dry, and leave them on the ground for 3 or 4 hours. Remove the tops, leaving about 1/2 inch of the crowns. Then pack into boxes or other well-ventilated containers, but without additional packing material. Store at 32°F to 34°F and 90 to 95 percent humidity (moist), with little air circulation. Jerusalem artichokes will freeze at just below 31°F. Store in a basement storage room or root cellar for 2 to 5 months.

Kohlrabi

Choose late-maturing varieties and leave in the ground until after the first few frosts. Dig when the soil is dry, and leave on the ground for 3 or 4 hours. Remove the tops, leaving about 1/2 inch of the crown. Don't remove the roots. Pack in packing material in wooden boxes, barrels, plastic bags with air holes, or in a mound or buried barrel. Store at 32°F to 34°F at 90 to 95 percent humidity (moist), with just a little air circulation. Kohlrabi freezes at 30°F. Store in a basement storage room, mound, buried barrel, or root cellar for 1 to 2 months.

Leeks

Harvest with roots intact. Don't remove the tops. Set the roots firmly in moist dirt so the leeks stand upright. Keep the roots moist during storage, but don't water the leaves of the plant. Store at 32°F to 34"F and 90 to 95 percent humidity (moist), with some air circulation. Leeks freeze at just below 32"F. Store in a basement storage room, outside frame, or root cellar for 2 to 3 months.

Lentils, dried

Dried lentils won't freeze and will store well when properly dried and packaged. Dry them according to the instructions in "How to Dry Vegetables." Then store them at 32°F to 50°F and 65 to 70 percent humidity (dry), with some air circulation. Store In a dry shed or attic for 10 to 12 months.

Muskmelon

Harvest melons slightly immature; they will continue to ripen during storage. Store at 45°F to 50°F and 85 to 90 percent humidity (moderately moist), with some air circulation. Pile or stack melons loosely, with no packing material, on shelves in a basement storage room or root cellar for 2 to 3 weeks.

Onions

Dig up mature onion bulbs and leave them on the ground to dry completely, usually about a week. Cut

off the tops, leaving 1/2 inch of stem. Pack the bulbs loosely, without any packing material, in well-ventilated containers. If you like, braid the tops together and hang the onions from hooks in a cold storage area. Store at 32°F to 34°F and 60 to 75 percent humidity (dry), with some air circulation. Onions freeze at just under 31°F. Store in a dry shed or attic for 6 to 7 months.

Parsnips

Choose late-maturing varieties and leave them in the ground until after the first few frosts. Dig them up when the soil is dry, and leave them on the ground for 3 or 4 hours. Remove the tops, leaving about 1/2 inch of the crown. Don't remove the roots. Pack in packing material in wooden boxes, barrels, plastic bags with air holes, or in a mound or buried barrel. Store at 32°F to 34°F and 90 to 95 percent humidity (moist), with a little air circulation. Parsnips freeze at 30°F. Store in a basement storage room, mound, buried barrel, or root cellar for 2 to 6 months.

Peanuts, dried

Dried peanuts won't freeze, and will store well for 10 to 12 months when properly dried and packaged. Dry them according to the instructions in "How to Dry Vegetables." Then store them at 32°F to 50°F and 65 to 70 percent humidity (dry), in a dry shed or attic.

Peas, **dried**
(shelling, black-eyed)

Dried peas won't freeze, and will store well when properly dried and packaged. Dry them according to the instructions in "How to Dry Vegetables." Then store them at 32°F to 50°F and 65 to 70 percent humidity (dry), with some air circulation. Store in a dry shed or attic for 10 to 12 months.

Peppers

Harvest before the first frost. Choose only the firmest peppers for storing, since they're easily damaged. Pack into plastic bags punched with air holes; then place in boxes. Peppers must be monitored very carefully during storage to be sure they don't become too moist or too cold. Store at 45°F to 50°F and 85 to 95 percent humidity (moderately moist), with a little air circulation. Peppers will freeze at just below 31°F. Store in a basement storage room or root cellar for 2 to 3 weeks.

Potatoes

Choose late-maturing varieties. Early potatoes are difficult to keep in cold storage. Dig the potatoes when the soil is dry, and leave them on the ground for 3 or 4 hours. Avoid sun and wind damage. Cure by storing them at regular basement temperatures — 60°F to 65°F—in moist air for 10 days. Then pack them into boxes or other well-ventilated containers, but without additional packing material. Store at 38°F to40°F, and 85 to 90 percent humidity (moderately moist), with a little air circulation. Potatoes will freeze at just below 31°F. Store in a basement storage room or root cellar for 4 to 6 months.

Pumpkins

Harvest just before the first frost, leaving an inch or so of stem. Cure at 80°F to 85°F for 10 days, or for 2 to 3 weeks at slightly lower temperatures. After curing, move them to a cooler spot for long-term storage. Store at 50°F to 55°F and 60 to 75 percent humidity (dry), with a little air circulation. Pumpkins will freeze at just above 30°F. Store on shelves in a basement storage room, dry shed, or attic for 3 to 6 months.

Rutabagas

Choose late-maturing varieties and leave them in the ground until after the first few frosts. Dig them up when the soil is dry, and leave them on the ground for 3 or 4 hours. Remove the tops, leaving about 1/2 inch of the crowns. Don't remove the roots. Pack in packing material in wooden boxes, barrels, or plastic bags with air holes, or in a mound or buried barrel. Store at 32°F to 34°F and 90 to 95 percent humidity (moist), with a little air circulation. Rutabagas will freeze at about 30°F. Store in a basement storage room, mound, buried barrel, or root cellar for 2 to 4 months.

Salsify

Harvest in late season. Dig them up when the soil is dry, and leave them on the ground for 3 or 4 hours. Remove the tops, leaving about 1/2 inch of the crowns. Don't remove the roots. Pack in packing material in wooden boxes, barrels, plastic bags with air holes, or in a mound or buried barrel. Store at 32°F to 34°F and 90 to 95 percent humidity (moist), with a little air circulation. Salsify freezes at about 30°F. Store in a basement storage room, mound, buried barrel, or root cellar for 2 to 4 months.

Seed^ live

Most gardeners buy seeds to plant, but you may want to harvest seeds to sprout when your vegetables mature. Cabbage and lettuce seeds, for instance, can both be sprouted, as detailed in "How to Sprout Vegetables." Leave the seeds on the plant until they're dry and fully mature; then harvest them. Store dried seeds in airtight plastic bags in a metal container, or in airtight glass jars; keep glass jars in a bag or wrap in newspaper to keep light from reaching the seeds. Store at 32°F to 40°F and 65 to 70 percent humidity (dry). Store in a dry shed or attic for 10 to 12 months.

Shallots

Dig up mature bulbs and leave them on the ground to dry completely, usually about a week. Cut off the tops, leaving about 1⁄2 inch of stem. Pack the bulbs loosely, without any packing materials, in well-ventilated containers. Store at 32°F to 34°F and 60 to 75 percent humidity (dry), with some air Circulation. Shallots freeze at just under 31°F. Store in a dry shed or attic for 2 to 8 months.

Soybeans^ dried

Dried soybeans won't freeze, and will store well when properly dried and packaged. Dry them according to the instructions in "How to Dry Vegetables." Then store them at 32°F to 50°F and 65 to 70 percent humidity (dry), with some air circulation. Store in a dry shed or attic for 10 to 12 months.

Squashy winter

Harvest just before the first frost, leaving on an inch or so of stem. Cure at 80°F to 85°F for 10 days, or for 2 to 3 weeks at slightly lower temperatures. After curing, store at 50°F to 60°F and 70 to 75 percent humidity (moderately dry), with some air circulation. Squash freezes at just above 30°F. Store in a basement storage room, root cellar, dry shed, or attic for 5 to 6 months.

Sweet potatoes

Choose late-maturing varieties. Put sweet potatoes directly into storage containers when you harvest them. Cure them under moist conditions at 80°F to 85°F for 10 days. At lower temperature, curing takes longer—2 to 3 weeks. Stack storage crates and cover them to hold in the humidity while curing. After curing, store at 55°F to 60°F and 85 to 90 percent humidity (moderately moist), with some air circulation. Sweet potatoes freeze at just below 30°F. Store in a basement storage room or dry shed for 4 to 6 months.

Tomatoes, green

Plant late so the vines will still be vigorous when you pick the tomatoes for storage. Harvest green tomatoes just before the first killing frost. When you harvest, remove the stems from the tomatoes, then wash and dry them before storing. Be careful not to break skins.

Separate the green tomatoes from those that are showing red. Pack green tomatoes 1 or 2 layers deep in boxes or trays; you can also ripen a few tomatoes for immediate use by keeping them in closed paper bags in the house and out of the direct sun. Store green tomatoes at 55°F to 60°F and 85 to 90 percent humidity (moderately moist), with good air circulation. At room temperature mature green tomatoes ripen in 2 weeks; at 55°F, ripening will be slowed down to nearly 1 month. Immature green tomatoes will take longer to ripen at either temperature; tomatoes showing some red will ripen faster, and can't be held in storage as long as totally green ones. Check your tomatoes once a week to monitor the ripening; remove the ripe ones and any that have begun to decay. Tomatoes will freeze at about 31°F. Store in a basement storage room or dry shed up to1 month.

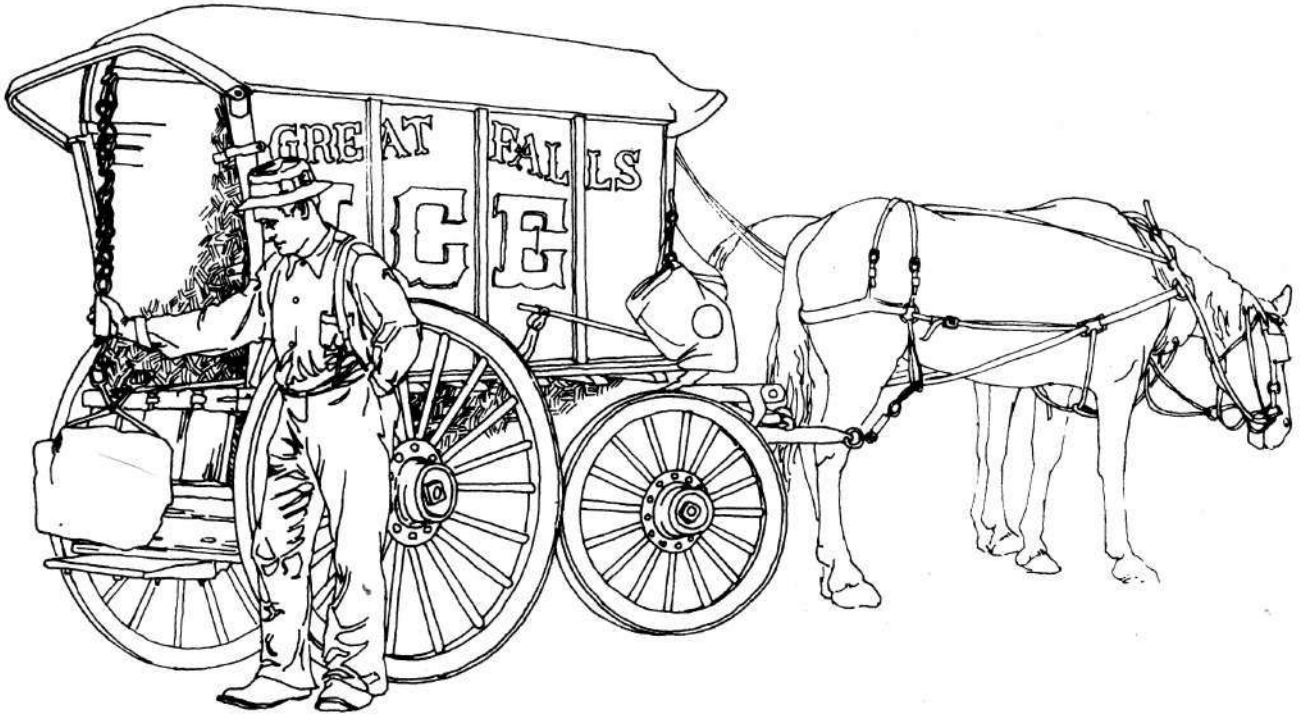
Turnips

Choose late-maturing varieties and leave them in the ground until after the first few frosts. Dig them up when the soil is dry, and leave them on the ground for 3 or 4 hours. Remove the tops, leaving about 1/2 inch of the crown. Don't remove the roots. Pack in packing material in wooden boxes, barrels, plastic bags with air holes, or in a mound or buried barrel. Since the strong odor of turnips can escape from the basement up into the house, it's wisest to store them separately and outdoors. Store at 32°F to 34°F and 90 to 95 percent humidity (moist), with a little air circulation. Turnips will freeze at about 30°F. Store in a mound or buried barrel for 4 to 5 months.

Watermelon

Harvest melons when fully ripe; they will not continue to ripen during storage. Store at 45°F to 50°F and 80 to 85 percent humidity (moderately moist), with some air circulation. Pile or stack melons loosely, with no packing material, on shelves in a basement storage room or root cellar for 2 to 3 weeks.

How to Freeze Vegetables



Freezing foods is one of the fastest and simplest methods of food preservation. It's easy to prepare food for the freezer and easy to prepare food for the table from the freezer. Best of all, foods preserved by freezing taste more like fresh than their canned or dried counterparts, and they retain more color and nutritive value.

Almost all vegetables take well to freezing. In fact, some vegetables shouldn't be preserved and stored by any other method. The list of better-frozen vegetables includes broccoli, Brussels sprouts, cabbage, cauliflower, eggplant, mushrooms, parsnips, edible-pod peas, pumpkins, rutabagas, and winter squash.

Although the techniques are simple and easy, freezing is a more expensive form of storage than canning. The freezer itself Is an investment, and it takes electricity to run. But if you manage your freezer wisely, it can still help you save on food costs.

Frozen vegetables can be stored a lot longer than many other foods, but shouldn't be kept stored for more than 12 months. By keeping your frozen foods in a constant state of turnover, the freezer space is being given maximum use. To get the most value from your freezer, use up the foods you've stored and replace them with others in season. The higher the rate of turnover, the lower the cost per pound of food.

Keep a list near the freezer to indicate what you've used, what's left, and what new foods you may be adding from time to time. By keeping track of what you have and how long it's been in the freezer, you'll be sure to use up all your frozen foods within the recommended storage period.

Getting started

Freezing is a simple method of food preservation and requires only a few steps. Having selected good-quaiity vegetables, then prepared and packaged them for freezing, you can sit back and let cold temperatures do the rest of the work.

Starting with the highest-quality vegetables and other foods is the single most Important factor In guaranteeing the quality of your frozen foods, but you must follow the directions for all freezing procedures exactly. Select the most perfect foods, and always exercise the strictest sanitary conditions and precautions when handling them. You can never be too careful about properly packaging and sealing foods for freezer storage.

If you follow freezing directions to the letter and keep food In a well-managed freezer, your frozen vegetables will be as delicious when you serve them as when you preserved them.

STOPPING THE SPOILERS

Extreme cold — and that means temperatures of 0°F or lower — is what stops the growth of the microorganisms In or around food that can cause spoilage. Zero temperatures also slow down enzyme activity and oxidation, which are chemical changes affecting the color, flavor, and texture of food. Although cold doesn't kill off these spoilers the way heating at high temperatures for canning does, freezing halts their activity during the time the food Is stored.

There are five major spoilers that can affect frozen food If it isn't handled properly:

- **Bacteria^ yeasts^ and molds** are normally present In all fresh foods. When these begin to multiply rapidly, spoilage occurs. You can stop these spoilers In their tracks by using the highest-quality vegetables and other foods, by preparing them under the most sanitary conditions, and by storing food at the specified, very cold temperatures.
- **Enzymes,** also normally present in all food, work to bring about chemical changes In it. These changes result in spoilage — unless enzyme activity is stopped before food is frozen, enzymes can destroy the fresh flavor of vegetables and cause them to take on an off-color. You can stop enzyme activity by blanching vegetables (a brief heat treatment) before freezing them.
- **Freezer burn** affects foods that haven't been wrapped carefully enough. If exposed surfaces on the food come in contact with the dry air of the freezer, moisture Is lost, and dry, tough surfaces develop. You can control freezer burn by using moisture vaporproof packaging materials that are airtight when sealed.
- **Large ice crystals** occur when food isn't frozen quickly enough. Quick-freezing means storing foods at O°F or even subzero temperatures. If foods freeze too slowly, moisture from the cells in the food fibers forms ice crystals between the fibers, and the product loses liquid and may darken. Quick-freezing at zero temperatures locks the cells in the food fiber in their proper places.
- **Oxidation** is a chemical change that occurs when frozen foods are exposed to oxygen. The oxygen reacts chemically with other substances In the foods to create changes that affect the quality of that food. To prevent loss of quality due to oxidation, fill and seal your freezer containers correctly and carefully.

BASIC FREEZING EQUIPMENT

Except for the freezer and proper packaging materials, your kitchen is probably already supplied with most of the other pots, pans, and utensils you'll need for home freezing. This section is a guide to the tools and materials necessary for proper freezing of vegetables. And always remember that — no matter how good your equipment — it must be spotlessly clean and sanitary while you work, to prevent bacterial contamination.

Freezer containers

Preserving food by freezing is based on the principle that extreme cold (0°F) halts the activity of microorganisms, enzymes, oxidation, and other changes that cause food spoilage. When preserving foods by the heat treatment method of canning, containers must be hermetically sealed. Although that's not necessary for frozen storage, the packages you use *must* be airtight, as well as moisture/vaporproof, odorless, tasteless, and greaseproof.

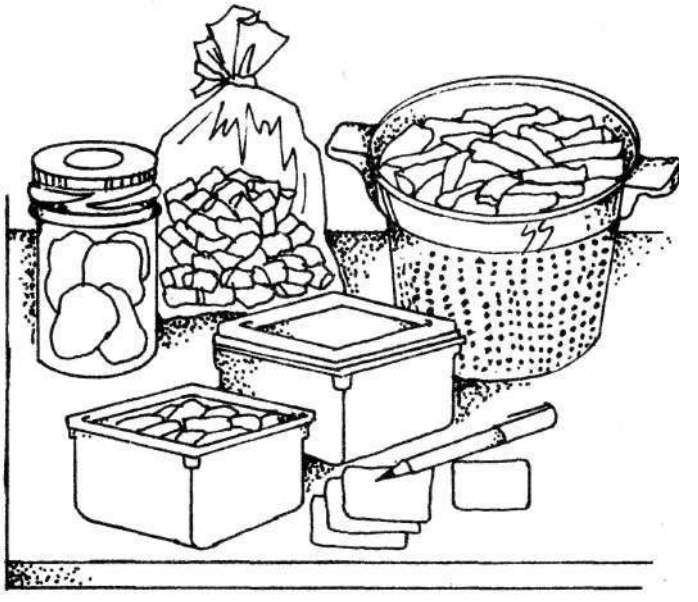
The best package size for you depends on your freezer and your family. Pack food in containers that will take care of your crew for one meal. You can plan on two servings to a pint container; three or four servings from a quart-size. It's quicker to thaw two single pint containers than one large container.

There are two kinds of freezer containers suitable for freezing foods at home — rigid containers and flexible bags or wrappers. Some delicate vegetables like asparagus or broccoli might be damaged if packaged immediately after blanching. To protect them, these vegetables are tray frozen briefly before being packed in freezer containers.

Rigid containers. Rigid containers are best for vegetables or foods that are liquid or don't have a distinct shape. Rigid containers include plastic freezer containers with tight-fitting lids or can-or-freeze jars with wide mouths and tight-fitting lids. Square or rectangular containers use freezer space more efficiently than round containers or those with flared sides or raised bottoms. Freezer containers can be reused. Wash them and their lids in hot suds; then rinse, drain, and cool.

Can-or-freeze jars come in three sizes: 1/2 pint, 1 pint, and 11/2 pints. Plastic freezer boxes come in 1-pint, 11/2-pint, 1-quart, and 2-quart sizes.

Freezer bags and pouches. Bags made from polyethylene or heavy-duty plastic or the new boilable pouches that can be heat-sealed are also good for freezing vegetables. Liquid foods are safest in plastic



Rigid containers and plastic freezer bags are both suitable for home freezing; or, if you prefer, use glass can-or-freeze jars. You will also need a blancher, labels, and a freezer marker.

bags that are then placed in protective cardboard boxes. Although bags aren't always easy to stack, they're great for tray-frozen vegetables and bulky or odd-shaped items.

Plastic freezer bags come in many sizes: 1 pint, 11/2 pints, 1 quart, 2 quarts, 1 gallon, and 2 gallons you close these bags by pressing out the air, twisting the top and doubling it over, then wrapping the top several times with a twist tie.

Other packaging materials. Never use empty, plastic-coated milk cartons or cottage cheese or ice cream containers for freezing, since these aren't airtight enough to be reused as freezer containers. Lightweight plastic wrap, butcher paper, and waxed paper aren't tough enough to protect food in the freezer, either. Freezer wrap — specially laminated or coated freezer paper, heavy-duty plastic wrap, or heavy-duty aluminum foil — is seldom used for freezing vegetables. Reserve it for meats, fish, game, casseroles, and cakes.

The freezer

In this book, all references to a freezer mean a separate appliance for freezing only. The ice-cube

section of a refrigerator is good for very short-term storage only, and "short-term" means days, not weeks or months. The separate freezing compartment of a refrigerator can hold food for weeks; a side-by-side freezer section can hold food for a few months. But, for long-term storage at 0°F, a separate household freezer is still your best bet.

Three types of freezers. There are three types of home freezers from which to choose. *Upright freezers* range in size from 6 to 22 cubic feet and may have 3 to 7 shelves. *Chest freezers* run from 6 to 32 cubic feet. *Refrigerator-freezer combinations* range in size from 2 to 16 cubic feet of freezer space. Freezers with the frostless feature save you the work of annual defrosting, and keep frost from building up on food packages. (Frostless freezers should be cleaned annually.)

The freezer size and type you buy will depend on your needs and available space. A chest freezer usually costs less to buy, and to run, but an upright may fit into your home more easily. Most folks agree that it's easier to find and remove foods from an upright freezer, too. In a combination model, the freezer is separated from the refrigerator section, having a separate door, either at the top, bottom, or side of the refrigerator. Check your space and your budget to decide which type is best for you.

Plan on 6 cubic feet of freezer space per person in your family. Then, if you can manage it, buy a freezer bigger than that. Once you get used to having a freezer, you'll have no trouble filling it.

Whichever freezer type you choose, place it in a cool, dry, and well-ventilated location. Before you start shopping, scout out a good location in your home, measure it, and check your doorway measurements to be sure the freezer you buy will fit through them.

Adjusting freezer temperature. Keep track of your freezer's temperature with a refrigerator-freezer thermometer. Put it toward the front of the storage area, fairly high up in the load of food. Leave it overnight — without opening the freezer — before you check it for the first time. If the thermometer reads above 0°F, adjust the freezer's temperature control to a lower setting. Wait another day and check the thermometer again to see if you adjusted the temperature correctly. When you've got the temperature just right, check the thermometer once a day. But, if your freezer has an automatic defrost, don't take a reading during the defrost cycle — it won't be an accurate reflection of normal freezer temperature.

Managing your freezer. For the most efficient use of your freezer, you must be organized. Think of your freezer as a warehouse or a food depository. You need to keep track of what's inside, when it went in, and when it should come out. "First in, first out" is the byword for the best in flavor and appearance in frozen food. The food is still safe to eat after 12 months, but may not be at the peak of its quality. As a rule of thumb, rotate your entire stock about every six months, or freeze only enough vegetables to last until the next growing season.

By grouping like **with** like in your freezer, your inventory will be more organized and your searching simplified. One shelf or section can keep vegetables, another fruits, another cooked foods or main dishes. Devise an inventory form to help you keep track of where each category of food is. You might put the chart on a clipboard hung on the freezer door handle or nearby. Then note what goes in, out, how much, and when. Don't forget to label each and every package clearly — in writing or symbols someone besides yourself can read! Legible labels and good packing in the freezer make inventory and food selection easy.

As you use your frozen food, keep a running check on your methods and packaging. If you notice that a particular bag, container, or sealing method isn't doing the job, make a mental note of it and try another procedure or packaging next time.

Caring for your freezer. Take care of your freezer according to the manufacturer's directions. By keeping the freezer defrosted, free of ice, and clean, it'll work better and cost you less to operate. A full or almost-full freezer is cheaper to run than an empty or almost-empty one. The higher the turnover — the more you use and replace frozen foods — the less your freezer "warehouse" costs per item.

If your freezer needs an annual or semi-annual defrost, do it while the weather is cold, preferably before you start planning your garden. During a defrosting in cold weather, not only can the food wait outside (in well-insulated boxes or coolers), but you can take a thorough inventory and then determine how much to plant in spring. If you have lots of green beans left in March, that's a clue that supply is exceeding demand. Put up less the coming year and fill that freezer space with something else.

To defrost your freezer, follow manufacturer's directions. If you don't have directions, remove food to a cold place — outdoors in a cooler, if the Weather is very cold or placed in a neighbor's freezer, or a locker. Unplug or turn off the freezer, and put in a pan or two of hot water or a blowing fan to help hurry the melting. DON'T use a hair dryer or other heating appliance, because the heat could melt or warp some of the materials on the inside of the

freezer. As the ice loosens, scrape it off with a plastic windshield scraper or other similar tool. When all the ice is gone, wash the inside of the freezer with a solution of three tablespoons baking soda dissolved in a quart of warm water. Wipe dry, turn the freezer on, and put the food back in. Clean frostless freezers with a baking soda solution annually.

If your freezer develops an odor, put a piece or two of charcoal on a paper towel and set them in the freezer a few days.

What to do when the freezer goes out. if your freezer quits or the power goes out, there are several steps you can take to protect your frozen foods. First, set the freezer temperature at the lowest setting, then shut the freezer and DON'T OPEN IT UNLESS ABSOLUTELY NECESSARY. If kept closed, a full freezer will keep food frozen for 15 to 20 hours and food will stay below40°F for up to 48 hours. A half-full freezer may keep foods frozen for just under a day.

If the freezer will be off for longer, dry ice could save the day, if you act quickly. (It's a good idea to locate a source of dry ice in advance and keep the name and number handy for just such an emergency.) A 25-pound chunk of dry ice, carefully handled with gloves and placed on a piece of heavy cardboard on top of the packages of food, should hold a half-full freezer (10 cubic feet) for two to three days; if the freezer is full, it will carry you over for three to four days. (Use two-and-a-half pounds of dry ice for each cubic foot.) Be sure the room is well-ventilated when you're working with dry ice.

If dry ice is unavailable, pack up the food and use a locker or a neighbor's freezer.

If the food's temperature rises above 40°F — ordinary refrigerator temperature — check it over carefully and immediately cook it completely. It's always better to use thawed foods immediately. If you do refreeze thawed foods, use them as soon as possible. If the food shows any signs of spoilage — color or texture change, slipperiness, or off-odor — and has been over 40°F, don't take any chances — toss it out. A freezer thermometer is an excellent guide to freezer safety. If you don't have a thermometer, feel the food and take a guess. Anything that's still frozen solid, and still has ice crystals throughout, is safe to refreeze or use if you're quick about it.

The blancher

Vegetables are precooked slightly before freezing in order to arrest the chemical changes that are caused by enzyme activity. This brief heat treatment is called blanching, and you'll need a blancher to do it properly. A blancher is a large pot, with a cover and a perforated insert or basket insert for lifting vegetables out of the boiling water. You can buy one in the housewares section of most stores, or you can make your own from a large (6- to8-quart) pot with a cover and something (a colander, sieve, deep frying basket, or cheesecloth bag) to lift the vegetables from the boiling water.

When you aren't using the blancher for freezing vegetables, it won't gather dust. It can also be used as a spaghetti cooker, steamer, or even a deep-fat fryer.

Other basic equipment

Besides the freezer and blancher, the basic equipment for freezing consists of whatever kitchen implements you'll need to prepare the food for packaging. Remember that it's essential to keep equipment, work area, and hands clean.

To freeze vegetables successfully, you'll need:

- Rigid freezer containers with airtight lids for liquid foods: plastic freezer containers; freezer cans or jars with wide mouths
- Bags: plastic storage bags; heavy-duty plastic bags; or boilable pouches
- String, rubber bands, pipe cleaners, or twist ties to fasten freezer bags
- Shallow tray, cookie sheet, or jelly-roll pan for tray freezing
- Additional heavy-duty plastic wrap or heavy-duty aluminum foil
- Sharp paring knife
- Chopping knife
- Colander, sieve, strainer, or paper towels
- Stiff vegetable scrubbing brush
- Teakettle for extra boiling water
- Ricer, food mill, or blender for mashing or pureeing
- Freezer tape to seal wrapped foods and to make labels
- Grease pencil or felt-tip marker or pressure-sensitive labels for labeling packages

BASIC INGREDIENTS

Choose vegetables that are tender, ripe but just barely ready to eat, and just as fresh as possible. Slightly under-mature vegetables are better for freezing than those that are past their prime. For peak flavor, rush vegetables from the garden to the freezer within two hours. If you can't freeze vegetables within that time limit, cool the vegetables quickly in ice water, drain well, and keep

refrigerated until ready to prepare for freezing.

Ice. Since cooling is an important part of preparing vegetables for freezing, you need plenty of Ice at hand to keep the cooling water really cold. Estimate one pound of ice for each pound of vegetables you're going to freeze. Keep a good store of ice in reserve for your home freezing heeds by filling heavy-duty plastic bags with ice cubes, or freezing water in empty milk cartons. Keep adding to your stored ice from time to time, and you won't be caught short in the midst of a big freezing job.

Butter and seasonings. Most vegetables are frozen without any flavoring or seasoning added. However, if you want to freeze pouched vegetables in butter sauce, we suggest a combination of butter, salt, and herbs (oregano, basil, savory, chervil, tarragon, thyme, sage, or marjoram).

BASIC FREEZING TECHNIQUES

Although freezing food is one of the easiest methods for putting food by, that doesn't mean there's nothing to it. If you approach the project carefully and scientifically, you'll be able to get the best frozen food possible and to use energy wisely.

Most vegetables take well to freezing, and, when you serve them at a later date, they'll be as close to fresh as any preserving method can guarantee. In fact, some vegetables shouldn't really be stored by any other method, since freezing has proven to be the best method for preserving them. These include broccoli, Brussels sprouts, cabbage, cauliflower, , eggplant, mushrooms, parsnips, edible-pod peas, pumpkins, rutabagas, and winter squash. The only vegetables that don't freeze well are lettuce and other fresh greens for salads, and watery vegetables like radishes and cucumbers.

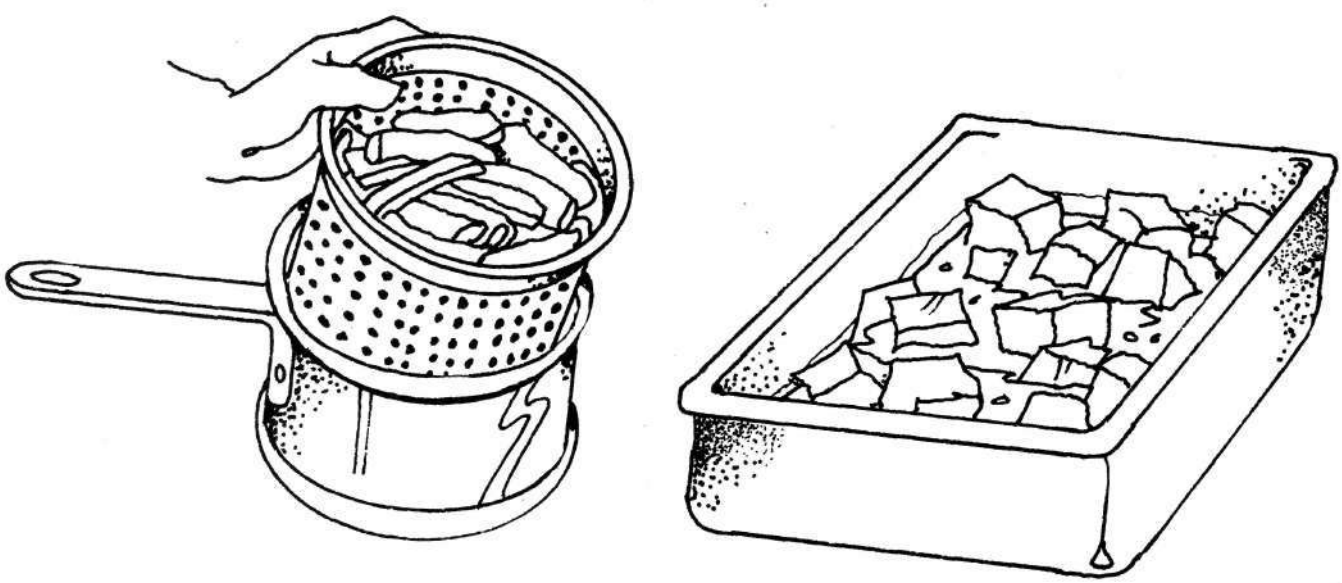
Other than those, almost anything can be frozen. When you aren't sure whether you'll like a certain vegetable frozen, try a sample batch of just a few packages, bags, or containers. Freeze for a couple o1 weeks, then taste. If you hate it, not much has been lost.

It's a good idea to check with your local Cooperative Extension Service Office for advice on the best vegetables to plant for freezing. Knowledgeable produce people, either in the supermarket or at a stand, can be excellent sources of information, too.

Selecting the vegetables

Rule number one is to select the highest-quality food possible. The vegetables you choose should be tender, fresh, and ripe enough to be eaten right away. NEVER use vegetables that have become overripe either before or after harvesting.

As with any preserving method, you must clean



Vegetables should be blanched before freezing to arrest enzyme action. To blanch properly, use a blancher with a perforated insert; blanch for the time recommended in each recipe. Transfer blanched vegetables quickly to a large pan of ice water to stop the cooking process.

vegetables carefully before freezing. Wash, scrub, rinse, and drain them just as if you were going to eat and serve them right away.

Blanching

Blanching is a brief heat treatment given to vegetables before they're packaged and frozen. Its purpose is to stop the action of enzymes, which can destroy the fresh flavor of vegetables and cause off-colors. If you want to successfully freeze vegetables, it's generally necessary to blanch them before freezing. This simple technique also helps seal in vitamins, brightens the color of vegetables to be frozen, and shrinks them slightly to make packing easier. When freezing herbs or vegetables such as green onions or hot peppers, which are to be used for flavoring only, blanching *isn't* necessary.

Follow blanching times given in the freezing recipes precisely. Blanching for too short a time is worse than not blanching at all — enzyme action will be stimulated instead of stopped. And, if blanched for too long a time, your vegetables will cook, losing vitamins, minerals, flavor, and color.

Use one gallon of water per pound of vegetables, or two gallons for leafy greens. Blanching water must be boiling when you lower the vegetables into it. Fill the blancher with vegetables and lower it into boiling water; start timing as soon as the vegetables have gone into the boiling water. You may keep the blancher covered during the blanching period or keep the heat on high and stir frequently. If you live at 5,000 feet or more above sea level, blanch one minute longer than the times specified in each recipe. You can also blanch vegetables in a microwave oven. Follow the directions in the manufacturer's instruction book.

When blanching a large quantity of vegetables, start with only the amount that can be blanched and cooled in a 15-minute period, and put the rest in the refrigerator. Package, label, and freeze each blanched group before starting on the next. You can use the same blanching water for several batches of vegetables, adding additional boiling water from a teakettle to replace water lost through evaporation. If you wish, change the water when it becomes cloudy. Keep a second pot or large teakettle boiling, so you won't be delayed when the time comes to change the blanching water.

Cooling

After vegetables have been precooked the exact amount of time, remove them immediately from the boiling water and cool them. This is crucial for keeping the heating process from continuing past the proper period for each vegetable or food. Transfer the vegetables quickly from the blancher to the ice water. The kitchen sink is a good spot for holding ice water to cool vegetables, but if you want it free for other uses, put the ice water in a plastic dishpan or other large, clean container.

Be sure to add new ice to the Ice water frequently, so it stays as cold as possible. You'll need plenty of ice on hand to keep the cooling water really cold. Plan on one pound of ice for every pound of vegetables you're going to freeze. To have a ready supply when you need it, you'll have to stock up in advance.

Packing and sealing

The secret to successful freezer packaging is to seal the air out and keep it out. Immediately after blanching and cooling, pack vegetables loosely in proper containers. Plastic freezer bags and boxes or can-and-freeze jars are all excellent. Freezer containers must be airtight, moisture/vaporproof, odorless, tasteless, and greaseproof.

Head space. Since food expands as it freezes, you must allow room — or head space — for this expansion. Otherwise the lids will pop off, bags will burst, and you'll have wasted food, time, and money. Foods that are dry need no head space. Food that's packed in liquid or is mostly liquid needs 1/4 inch of head space for pints, 1/2 inch for quarts. If you pack foods in containers with narrow mouths, the food expands upward in the container even more, requiring^ inch of head space for pints and iy2 inches for quarts. We suggest you stick to wide-mouth containers. The recipes in this book give you head space needs for each particular food for wide-mouth containers only.

Sealing. How you seal food for the freezer is just as important as how you package it. After wiping the mouths of your freezer containers with a clean, damp cloth, seal rigid containers by following the manufacturer's instructions (if there are any), or by snapping, screwing, or fitting the lid tightly on the container. If the lid doesn't seem tight, seal it with freezer tape.

Seal bags or boilable pouches with a heat-sealing appliance; follow the instructions that come with the heat sealer. Or seal bags by pressing out the air, then twisting the bag close to the food. Fold the twisted section over and fasten it with a rubber band, pipe cleaner, or twist tie. To get air out of an odd-shaped bag, lower the filled bag into a sink full of water and let the water press the air out. Twist the bag top, lift it out, double the twisted area backward, and fasten.

Labeling. A good freezer label should tell what food is in the package, the amount of food or number of servings, and when it went into the freezer. Better yet, it should tell how the food was packed, and when, for example, "Sugar Pack Strawberries — June, 1976." You might want to include an "expiration" or "use-by" date. Frozen main dishes, sauces packed in boilable pouches, and other more complex items call for a label with description, number of servings, perhaps even heating and thawing instructions.

Select labeling materials that will last. A grease pencil or felt tip marker may write directly on the container. Freezer tape makes a quick label, as do pressure-sensitive labels from a stationery store. Try to print legibly and use standard abbreviations.

Tray freezing. This technique is used with more delicate vegetables — asparagus for example — to keep them from being damaged during packaging. Since individual stalks are frozen separately first, tray freezing allows you to remove serving portions from the pouch when you need them. To tray freeze, blanch the vegetables, cool them in ice water, drain well, and then spread in a single layer on a cookie sheet, jelly-roll pan, or special tray. Freeze until just solid — usually about an hour. As soon as the vegetables are frozen solid, transfer them to containers, bags, or pouches. Seal the containers and store them in the freezer.

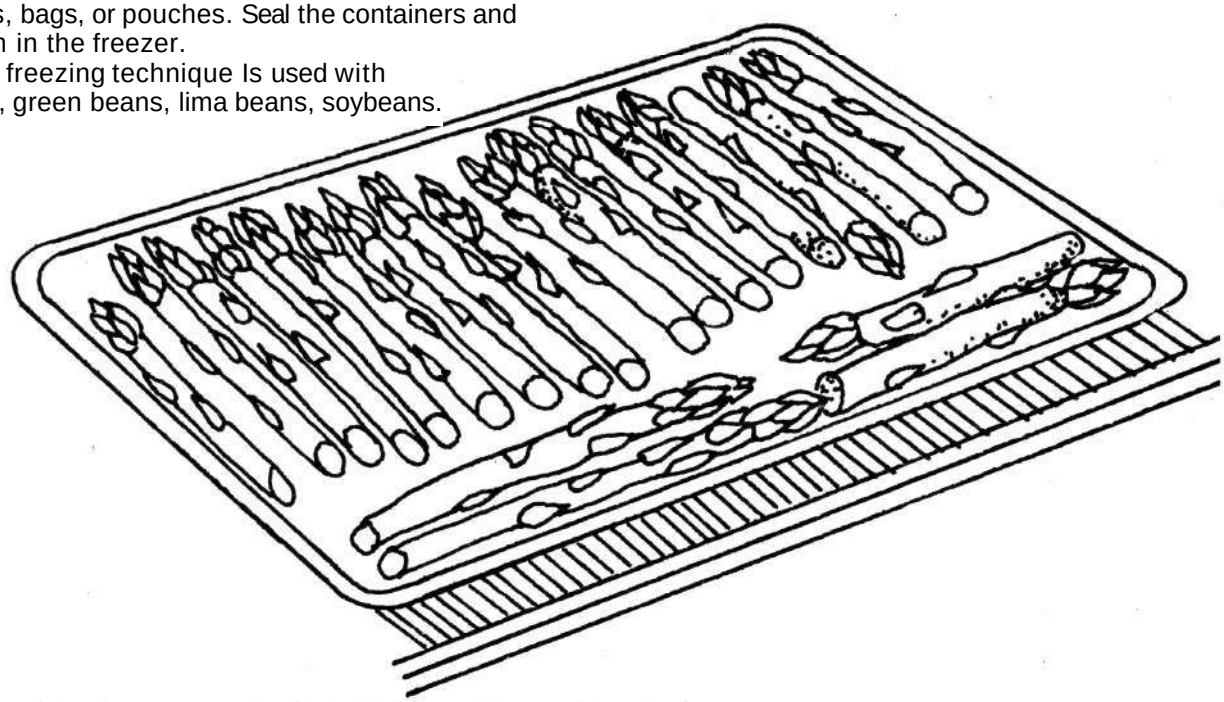
The tray freezing technique Is used with asparagus, green beans, lima beans, soybeans. broccoli, Brussels sprouts, cauliflower, whole- * kernel corn, kohlrabi, peas, sweet or hot peppers, prepared potatoes, rutabagas, and summer squash. The recipes that follow indicate if tray freezing is recommended.

Quick-freezing

Put your sealed freezer packages in the coldest spot in your freezer, which should be set at 0°F. Place the containers in a single layer, leaving a little space between each package for heat to escape — or follow any specific freezing directions given by the manufacturer. Be sure to set the freezer temperature control to the lowest setting several hours *before* you'll be preparing food for freezing.

Look back to the use-and-care book that came with your freezer to locate the coldest sections. If you have an upright freezer, the shelves are the coldest places; in a chest freezer, the coldest places are near the walls. In a combination refrigerator-freezer, the shelves inside the freezer—not the door shelves — are the coldest places.

After arranging packages in a single layer, shut the freezer and leave it alone for 24 hours. When that time has elapsed, the food should be frozen solid. Stack it up and move it away from the coldest part to



Delicate vegetables like asparagus should be briefly tray frozen before they're packaged. Spread the blanched vegetables in a single layer on a cookie sheet or tray, and freeze them until just solid. Then transfer the frozen vegetables to containers and store them in the freezer.

another area in the freezer for storage. Then you can add another batch to be frozen.

Your freezer can only freeze a limited amount of food at a time, usually two to three pounds of food for each cubic foot of freezer space. Don't try to freeze any more than that or the food will freeze too slowly and quality will be lowered. The amount of food your freezer can freeze at once helps you determine how much food to prepare for the freezer on any particular day. If you have more food to be frozen than your freezer can take, either refrigerate packages for a day or so (not much longer), or cart it all to a locker to be frozen, then transfer it to your home freezer. Always try to keep a cold spot free to quickly freeze additional food.

When you're done freezing food In quantity, reset the control to the setting that will maintain 0°F.

Serving frozen vegetables

Most frozen vegetables should be cooked without thawing. Corn-on-the-cob is a major exception; it must be thawed completely before cooking. Greens should be partially thawed in order to separate the individual leaves before cooking. Vegetables fully cooked before freezing should also be partially thawed before heating. Once they're thawed, use your vegetables as quickly as possible. Food that's been frozen spoils more quickly than fresh food.

Cooking frozen vegetables. For best results, cook frozen vegetables just as you would fresh ones — but cook them for a shorter period, since blanching shortens cooking times. Prepare only the amount of vegetables you'll consume at one meal, and use as little cooking water as possible.

For each pint of frozen vegetables, heat 1/4 to 1/2 cup water to boiling in a small or medium saucepan. Add the vegetables and keep them over high heat until the water returns to a boil. Break vegetables into individual pieces with a fork as they heat. When the water boils again, cover the pan, reduce the heat, and simmer just until the vegetables are tender. The recipes in this book give specific postfreezing cooking times for each vegetable. Begin timing when the cooking water returns to a boil. When crisp-tender, add butter or margarine, salt, pepper, or other seasonings to taste. Serve vegetables immediately after cooking, so they won't lose nutrients.

For tray-frozen vegetables, just remove the amount you need from the freezer. Increase cooking water to a little more than 1/2 cup if you plan to serve more than 2 cups of vegetables. Cook as above.

For pouched vegetables, follow the cooking directions that come In the heat-sealer's instruction book.

Butter sauce for pouched vegetables. For each 1 to 11/2 cups vegetables in small boilable pouches, add 2 tablespoons water, 1 tablespoon butter, 1/4 to 1/2 teaspoon salt, and a dash oregano, basil, savory, chervil, tarragon, thyme, sage, marjoram, or other herbs appropriate to your vegetable. Seal, label, and freeze. Heat as the manufacturer directs.

Soups, casseroles, sauces, gravies, dips, and other mixtures need only be heated to serving temperatures. Baked goods such as zucchini bread or carrot bread can be served just after thawing.

Rules for safe freezing

For clean and safe-to-eat foods, always follow the freezing recipe directions exactly, use the containers and equipment called for, and keep in mind the following Do's and Don'ts:

DO

- Work in a clean kitchen with clean floors, counter tops, cabinets and range, and clean equipment.
- Keep utensils that handle raw meat and poultry scrupulously clean. That means scrubbing, washing, and rinsing knives and cutting boards between each type of cutting or chopping task.
- Work with clean food. Wash, scrub, and rinse vegetables in several waters, lift food out of the water to drain, and don't let water drain off over food.
- Work with clean dishcloths and towels, clean hands, and clean clothes.
- Wash your hands each time you touch something other than food, such as your hair, your face, the phone, a child, or a pet.
- Get out all the necessary equipment. Wash it and ready all ingredients before you start to follow recipe directions, so there'll be no delays and no chance for food to spoil.
- Remember to protect your hands when working with hot foods. Use hot pads and tongs.
- Be extra cautious with large pots or kettles of boiling water or food. Don't move them, but keep them on the range and work there.
- Avoid any sudden changes in temperatures when working with can-or-freeze jars. Putting a hot jar on a counter or in a cold draft could cause it to break.
- Always read and follow manufacturer's directions for special equipment or appliances.
- Use the very best, most perfect food for freezing. Spending time and money to freeze less than the best is a waste.
- Blanch all vegetables before freezing. Blanching destroys enzymes that can cause chemical

changes in foods, and is an essential step.

- Use moisture/vaporproof containers and seal properly, following recipe directions exactly. Poor packaging can cause freezer burn, off-flavors, and less-than-the-best foods.
- Freeze foods quickly to prevent large ice crystals from forming. Follow the directions for quick-freezing.
- Buy a freezer thermometer and check it regularly. It should read 0°F at all times — any higher temperature and you're shortening the freezer life of the food.
- Keep an inventory of your frozen vegetables, so you can use them within the best part of their freezer life. Most vegetables will maintain quality for a year. Vegetables that have been fully cooked before freezing should be stored for a much shorter time — no more than a month.
- Cook and serve vegetables as each recipe directs. Vegetables are best cooked directly from the frozen state, in a very small amount of water and just until tender.
- Put your freezer in a convenient, cool, dry, well-ventilated location and clean and/or defrost it once a year.

DON'T

- Don't use your hands when a kitchen tool will do the job. Keep fingers out of food if at all possible.
- Don't try shortcuts or substitutions or time-saving gimmicks. There's only one correct way to prepare food for freezing, and the techniques and recipes that follow are based on it.
- Don't cook or prepare food for preserving when you're sick.
- Don't prepare food if you have sores on your hands, unless you wear rubber gloves.

BASIC FREEZING STEPS

By now you can see that preparing vegetables for the freezer isn't too different from preparing them for dinner. However, you must always follow the freezing recipes exactly. The recipes in the next section give you specific instructions for each vegetable, but here is a summary of the basic steps:

1. Check your freezer's size and estimate how much food you can freeze in a 24-hour period (3 pounds of food for each cubic foot of space), then check the recipe for the vegetable you want to freeze to see how much to pick for a single preparation session.
2. Select tender, young, fresh vegetables that are unblemished.
3. Wash vegetables well in plenty of cold water, scrubbing with a brush whenever necessary. Lift the vegetables out of the water to drain. Don't let them stand in water any longer than necessary, because they lose nutrients. Sort by size and handle like sizes together for even heating and cooling.
4. Put 1 gallon of water (2 gallons for greens) in the blancher; cover, and place It over high heat.
5. Prepare the sink or dishpan full of ice cubes and ice water.
6. Cut or prepare the vegetables, about 1 pound or 4 cups at a time, as the recipe directs.
7. Put 1 pound of prepared vegetables in the blancher's Insert and lower it into rapidly boiling water. Keep the heat high. Cover and begin timing immediately.
8. When the time is up, remove the cover, lift the blancher's insert up out of the blancher for a few seconds to drain, then immediately put the insert of vegetables into ice water.
9. Keep vegetables in the ice water for about the same length of time as they were in the boiling water, or until cold. Stirring will help cool the vegetables.
10. Lift the vegetables from the ice water and drain them well in a colander, sieve, or on paper towels.
11. Pack into containers, bags, or freeze on trays.
12. Label each package with contents, number of servings, and date frozen. You might also wish to list an expiration date.
13. Freeze, following the directions for quick-freezing, or any special manufacturer's directions for your freezer.
14. Most vegetables will keep for 12 months at O°F.

How to Dry Vegetables

Drying is probably the oldest method of food preservation. Though canned and frozen foods have taken over the major role once played by dried foods, drying is still cheaper and easier by comparison. Some other advantages of dried foods are that they take up less storage space and will keep well for a long time — up to 12 months — if prepared and stored properly. Unlike frozen foods, they are not dependent on a power source. Though you may find canned and frozen vegetables are closer in taste and appearance to fresh food, you'll like having a stock of dried vegetables on hand to add variety and special flavor to meals.

STOPPING THE SPOILERS

Drying preserves vegetables by removing moisture, thus cutting off the water supply that would nourish food spoilers like bacteria, yeasts, and molds. The moisture content drops so low that spoilage organisms can't grow.

Although there's a definite technique to drying vegetables, it isn't quite as precise as the procedures used for freezing or canning. Unless you'll be using an electric food dryer, you'll have to use trial and error to find the best way to maintain the proper oven temperature throughout the drying process and to provide good ventilation so moisture from the food can escape. Drying times are given in the recipes for the individual vegetables, but these times are only approximate. Every oven is different, and drying times also depend on how many vegetables you're drying at once, how thinly they've been sliced, and how steady you've kept the heat. So you'll have to experiment at first with drying times. Experience is the best teacher when it comes to judging when your vegetables are dry enough to keep the spoilers from contaminating them.

Vegetables for drying

There are a great many vegetables you can dry at home for use in perking up your salads, soups, stews, and casseroles. Good vegetables to dry include green beans, corn, peas, peppers, okra, onions, mushrooms, tomatoes, and summer squash. Herbs also drywell. For more information on drying herbs, see "How to Store and Use Herbs," later in this book.

Although many vegetables drywell, some vegetables should be preserved by other methods for best results. For example, lettuce, cucumbers, and radishes don't drywell because of their high moisture content. Asparagus and broccoli are better frozen to retain their flavor and texture. And if you've got the storage space, you may find it more practical to store fresh carrots, turnips, parsnips, potatoes, pumpkins, rutabagas, and winter squash in cold storage where they'll keep for several months without any special preserving treatment.

FOOD DRYING METHODS

The sun, of course, Is the food dryer our ancestors used. If you live where Old Sol shines long, you too can dry fruits and vegetables outdoors. But those in less sunny regions will want a little help from a kitchen oven (gas, electric, convection, or microwave) or one of the new electric dryers or dehydrators. You can also make your own box dryer.

Oven drying is faster than using an electric dryer or dehydrator, but the electric dryers can handle much larger food loads than any of the ovens. Oven drying is best for small-scale preserving, since the ordinary kitchen model will hold no more than four to six pounds of food at one time. If you've got an extra-big vegetable garden and expect to dry food in quantity, you may want to investigate the new electric dryers or dehydrators, available in some stores and through seed catalogs. Several of the small convection ovens now on the market also have special racks available for drying vegetables. When using an electric dryer, or a convection or microwave oven for drying vegetables, always read and follow the manufacturer's directions.

Oven drying

Oven drying may be the easiest way for you to dry food, because it eliminates the need for special equipment. If you've never tried dried vegetables before, why not do up a small batch and sample the taste and texture?

Gas and electric ovens. Preheat your gas or electric oven to 140°F for drying vegetables; you'll need an oven thermometer that registers as low as 100°F in order to keep this temperature constant throughout the many hours of the drying process. Since ovens will vary, you'll probably have to experiment until you learn what works best with yours. For example, the pilot light on some gas stoves may provide just enough heat, or the light bulb in the oven may keep it warm enough for drying vegetables. Some electric ovens have a "low" or "warm" setting that may provide the right temperature for drying.

You must keep the oven door open slightly during drying, so moist air can escape. Use a rolled newspaper, wood block, hot pad, or other similar item to prop open the oven door about one inch for an

electric oven and four to six inches for a gas oven. Sometimes it also helps to place an electric fan set on "low" in front of the oven door to keep air circulating. Don't use a fan for a gas oven with a pilot light, though; it can blow out the pilot.

You'll be able to read the oven thermometer easily if you put it in the middle of the top tray of vegetables, take a reading after the first 10 minutes, and, if necessary, make adjustments in the door opening or the temperature control. After^ that, check the oven temperature every 30 minutes during the drying process to be sure it remains constant at 140°F.

To keep air circulating around the food, your drying trays should be one to two inches smaller all around than the interior of your oven. If you want to add more trays, place blocks of wood at the corners of the oven racks and stack the trays at least one-and-a-half inches apart. You can dry up to four trays at once in a conventional oven, but remember that a big load takes longer to dry than a smaller one. Don't use the top position of the oven rack in an electric oven for drying, because food on the top tray will dry too quickly.

Since the temperature varies inside the oven, it's important to shift your vegetable drying trays every half-hour. Rotate the trays from front to back, and shift them from top to bottom. Numbering the trays will help you keep track of the rotation order. You'll also need to stir the vegetables every 30 minutes, to be sure the pieces are drying evenly.

Convection ovens. To dry vegetables in a convection oven, arrange them on the dehydrating racks provided, and place the racks in a cold oven. Set the temperature at 150°F for vegetables, 100°F for herbs. The air should feel warm, not hot. Keep an oven thermometer inside the oven, so you can keep track of the temperature. Prop the oven door open one to one-and-a-half inches to allow moisture to evaporate. Set the oven timer to the "stay on" position. Or, if your oven doesn't have a "stay on" option, set it for maximum time possible, then reset It during drying, if necessary. Drying times in a convection oven are usually shorter, so check foods for doneness at the lower range of times given in the recipes. Rotate the racks and stir the vegetables as you would using a conventional oven.

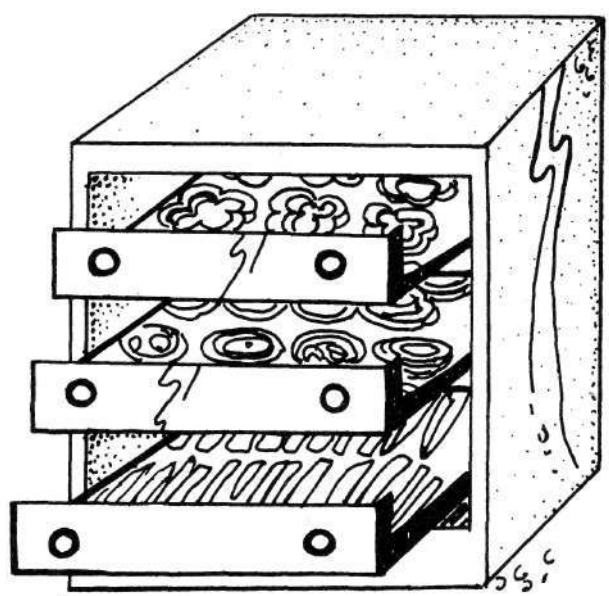
Microwave ovens. To dry foods in a microwave oven, follow the directions that come with your appliance. Usually, you arrange the prepared vegetables in a single, even layer on paper towels, cover them with more paper towels, and then dry the food at a reduced power setting. If you have a microwave roasting rack, arrange the vegetables on It before drying. Stir the vegetables and replace the paper towels with fresh ones periodically. Exact drying times can vary widely, depending on the wattage and efficiency of your oven, the food itself, and the humidity, so you'll need to check frequently *and* keep a record of best drying times for reference.

Food dryers

Both commercial and homemade food dryers provide automatically controlled heat and ventilation. You can buy the new electric dryers or dehydrators in many hardware, housewares, farm supply, and health food stores. Prices range from $25 to $100, depending on the size of the appliance and other special features. Or you can make your own drying box, following the directions given below.

Electric dryers or dehydrators. These are lightweight metal boxes with drawer racks for drying foods, which will hold up to 14 pounds of fresh vegetables. If you'll be doing a great deal of home drying, look into an electric dryer, because drying large quantities of vegetables could tie up your kitchen oven for days at a time. Although electric dryers use less electricity for drying than would an electric oven for the same amount of vegetables, electric dryers run at lower temperatures and drying times are a bit longer.

When using an electric dryer or dehydrator, always follow the manufacturer's directions for drying foods.



An electric dryer, or dehydrator, is a wise buy if you're drying large quantities of vegetables at home; it takes a little longer than your electric oven, but uses less energy.

Homemade drying box. A simple-to-make drying box can be constructed from a cardboard box, as in the instructions that follow. Or you may invent some other alternatives. For example, your radiators may send out enough heat to dry foods in winter, or perhaps your attic in the summer is hot and dry enough. Never use space heaters for drying vegetables, though — space heaters stir up dust and dirt, which contaminate the food.

How to make a drying box. A hardware or discount store should have everything you need to make this simple dryer:

- Either a metal cookie sheet with sides or a jelly-roll pan is needed to hold the food.
- An empty cardboard box (that has the same top dimensions as the cookie sheet) forms the drying box. The sheet should just fit on top of the box, or the rims of the sides should rest on the edges of the open-topped box.
- A box of heavy-duty or extra-wide aluminum foil is used to line the box.
- A small can of black paint is used to paint the bottom of the cookie sheet; buy a spray can or a small brush.
- A 60-watt light bulb and socket attached to a cord and plug provide the heat.

Line the inside of the box with foil, shiny side up. Cut a tiny notch in one corner for the cord to run out. Set the light fixture in the center, resting it on a crumpled piece of foil. Paint the bottom of the cookie sheet black and let it dry.

Prepare the vegetables according to the recipe. Spread them in a single, even layer on the black-bottomed cookie sheet. Then put the sheet in place on top of the box. Plug in the light bulb to preheat the box and dry until the food is done according to the recipe. Each recipe specifies how to tell when food is sufficiently dry. If you're drying more than one sheet of food you II have to make more than one drying box. Don't prepare more food than you can dry at one time.

BASIC DRYING EQUIPMENT

Unless you decide to buy an electric dryer or dehydrator, you've probably already got everything necessary for home drying vegetables. In addition to an oven or a box food dryer, you'll need:

- A scale to weigh food before and after drying.
- An oven thermometer that will read as low as 100°F for maintaining proper oven temperature.
- Sharp stainless steel knives that won't discolor the vegetables, for thin-slicing, paring, or cutting the food in half.
- A cutting board for chopping and slicing. Be sure to scrub the board thoroughly before and after use.
- Baking or cookie sheets for use as drying trays. Unless you're making a box food dryer, cookie sheets without raised edges are best, since they allow hot air to circulate around all sides of the vegetables. (For microwave or convection oven drying, you'll need a special rack.) Baking or cookie sheets used for drying should be at least one to two inches smaller all around than the inside of your oven, so air can circulate.
- A blancher for pretreatment of most vegetables. Use a ready-made blancher; or make one using a deep pot with a cover, and a colander or gasket that will fit down inside the pot. For steam blanching, you'll need a rack or steamer basket.
- A long, flexible spatula for stirring the vegetable pieces to insure even drying.
- Airtight storage containers, with tight-fitting lids, that are also molsture/vaporproof. Use glass canning or other jars, coffee cans lined with plastic bags, freezer containers, or refrigerator-ware. You can also use double plastic bags; close them tightly with string, rubber bands, or twist ties.
- An electric fan to circulate the air in front of your oven, if necessary.

BASIC INGREDIENTS

Choose perfect vegetables that are tender, mature (but not woody), and very, very fresh. Vegetables must be prepared and dried immediately after harvesting, or they'll lose flavor and quality. Every minute from harvesting to the drying tray counts — so hurry. Never use produce with bad spots, and harvest only the amount of vegetables you can dry at one session.

Since vegetables must be chilled quickly after blanching, you'll need ice at hand to keep the cooling water really cold. Keep a reserve of ice in the freezer and you won't run short. One way is to start filling heavy-duty plastic bags with Ice cubes a few days before you'll be home drying; or rinse out empty milk • cartons, then fill them with water and freeze.

The kitchen sink is a favorite spot for holding ice water to chill vegetables, but if you want to keep it free for other uses, a plastic dishpan or other large, clean container also works very well.

BASIC DRYING TECHNIQUES

Although the techniques for drying vegetables aren't as precise as those for freezing or canning,

there's definitely a right way to go about it. As with all preserving methods, you must always begin with the freshest and highest-quality vegetables to insure good results. Cleanliness and sanitation when handling and preparing the food are also crucial. And, though drying vegetables isn't difficult to do, it demands plenty of careful attention. The vegetables must be stirred, the temperature checked, and tray positions changed about every half hour. That means you must be at home during the whole time it takes to dry your vegetables.

Speed is of the essence when preparing foods to dry. For best results, vegetables should be blanched, cooled, and blotted dry within a very short time of harvesting. And you must never interrupt the drying process once it's begun. You can't cool partly dried food and then start it up again later, because there's a chance bacteria, molds, and yeasts will find a home in it. Always schedule your home drying for a day when you're certain your work won't be interrupted.

Cleaning and cutting

Harvest only as much food as you can dry at one time. Using a kitchen oven, that's about four to six pounds; an electric dryer or dehydrator can handle up to 14 pounds of fresh produce. Wash and drain the vegetables, then cut and prepare as the recipe directs. Depending on the size of the vegetables and the dryer, that could mean slicing, grating, cutting, or simply breaking the food into pieces so it will dry evenly on all sides. Remember that thin pieces dry faster than thick ones. If you have a choice between French-cutting and crosscutting green beans, remember that the French-cut beans will dry faster.

Blanching

Nearly all vegetables must be blanched before drying. Blanching—a brief heat treatment—stops the action of enzymes, those catalysts for chemical change present in all foods. If certain enzymes aren't deactivated before vegetables are dried, the flavor and color of the food will be destroyed. The drying process alone isn't enough to stop enzyme activity.

Although blanching can also help seal in nutrients, some other water-soluble nutrients are leached out into the cooking water. You may want to steam blanch your vegetables; it takes a bit longer, but won't lead to as great a loss of nutrients.

Always follow the blanching times given in the recipes exactly. Overblanching will result in the loss of vitamins and minerals; underblanching won't do the job of stopping enzyme action. Either way, you'll end up with an inferior product.

Boiling water blanching. Heat one gallon of water to boiling in a blancher. Put no more than one pound or four cups of prepared vegetables at a time into the blancher's insert, colander, or strainer, and carefully lower it into boiling water for the time given in the recipe.

Steam blanching. Pour enough water into the blancher to cover the bottom, but not touch the insert. Heat to boiling. Arrange the prepared vegetables in a single layer in the blancher's insert; put them in the blancher over boiling water, cover tightly, and steam for the time given in the recipe. You can use any large pot or kettle for steam blanching by putting a rack about three inches above the bottom to hold the vegetables in the steam and up out of the boiling water. You may also wish to put the vegetables in a cheesecloth bag to keep the pieces together during blanching.

Chilling

You must always chill blanched vegetables before drying them, to be certain the cooking process has stopped. After removing the vegetables from the blancher, immerse the colander or steamer rack full of vegetables in a sink full of ice water or a dishpan full of ice water. The vegetables should be chilled for the same amount of time the recipe gives for blanching in boiling water. Drain well, then blot with paper towels.

Preparing to dry

Spread the blanched and drained vegetable pieces in a single, even layer on the drying tray. (You can dry more than one vegetable at the same time, but strong-smelling vegetables such as onions, cabbage, and carrots should be dried separately.) Put the trays in the oven or electric dryer, leaving at least one to two inches between the trays for air circulation.

Maintaining **proper** drying temperature

Vegetables must be dried at low, even temperatures — just enough heat to dry the pieces without cooking them. The proper temperature for drying in a conventional oven is 140°F, 1S0°F for convection ovens. Follow the manufacturer's directions for microwave ovens and all other appliances. Maintaining the right temperature steadily, with some air circulation, is the trick to successful drying. Electric dryers and dehydrators automatically maintain the right temperature. For

oven drying or when using a homemade box dryer, check your oven thermometer every half hour. (To insure even drying, you must also stir the vegetables every 30 minutes or so, shift the trays from top to bottom, and rotate the trays from front to back.)

Although rapid drying is important, too rapid drying in an oven will result in the outer surface of the food hardening before the moisture inside has evaporated (case hardening). You can prevent case hardening by keeping a constant watch on the oven temperature and doing whatever is needed to maintain the heat at 140°F.

Scorching. Each vegetable has its own critical temperature beyond which a scorched taste will develop. Although there's not much danger of scorching at the start of the drying process, vegetables can scorch easily during the last couple of hours. Even slight scorching will ruin the flavor and affect the nutritive value of dried foods, so be extravigilant about maintaining the proper temperature toward the end of the drying process.

Ventilation. When vegetables are drying, the moisture they contain escapes by evaporating into the surrounding air. If the air around the food is trapped, it will quickly reach a saturation point. Trapped, saturated air won't be able to hold any additional moisture — and drying won't take place. For this reason, ventilation in and around your oven is as important as keeping the temperature constant.

Electric dryers or dehydrators automatically provide proper ventilation. With oven drying or when using a homemade box dryer, you'll need to leave the oven door slightly ajar — and possibly use an electric fan to insure good air circulation.

In addition, the cookie sheets or trays you use for drying should be at least one to two inches smaller all around than the inside of your oven so air can circulate around the front, sides, and back of the trays. There should also be at least three inches of air space at the top of the oven.

Testing for doneness

In most forms of food preserving, processing times are exact. You know just how long it takes before the food is done. However, the times for drying vary considerably — from four hours to more than 12 — depending on the kind of vegetable, how thinly it's sliced, how much food is on each tray, and how much is being dried in the oven or dryer at one time. The recipes that follow give you the drying time range for each vegetable, but the only way you can be sure the food is sufficiently dry is to test sample pieces.

When you think the vegetables are dry, remove a few pieces from the tray, then return the tray to the oven. Let the sample pieces cool before testing — even food that's perfectly dry will feel soft and moist while still warm. When the pieces are cool, follow the test for doneness given for the vegetable in each recipe. A rule of thumb is that properly dried vegetables are hard and brittle to the touch. Exceptions to the rule are mushrooms, sweet peppers, and squash, which will feel pliable and leathery when dry. Some food experts recommend the hammer test: if sufficiently dry, the vegetable pieces will shatter when struck with a hammer.

Conditioning

Foods don't always dry evenly, nor does each piece or slice dry at exactly the same rate as all the others. To be sure all the food in a single batch is evenly dried, you'll have to condition it. Put the cooled, dried vegetables into a large, deep crock, dishpan, jar, or coffee can; then store it in a warm, dry room for a week to 10 days. Cover the jar or can lightly with cheesecloth to keep out insects, and stir the dried pieces at least once a day so that the moisture from any underdried pieces will be absorbed by the overdried pieces.

After conditioning, give the vegetables one final treatment to get rid of any insects or insect eggs. Either put the dried vegetables in the freezer for a few hours, or heat them on a cookie sheet in a closed oven at 175°F for 15 minutes. Be sure to let the food cool completely again before packaging.

HOW TO STORE DRIED VEGETABLES

Keeping out air and moisture is the secret to good dried foods. To maintain the quality and safety of your dried vegetables, you'll need to take special care when packaging and storing them.

Even when you're using an oven or an electric dehydrator, you'll have to watch out for the effects of humidity on drying foods. Choose a bright, sunny day for your home drying—that way you'll keep the dried vegetables from picking up moisture from the surrounding air after they leave the oven or dryer.

Packaging

Dried foods are vulnerable to contamination by insects as soon as they're removed from the oven or electric dryer. To protect them, you must package dried vegetables in airtight, moisture/vaporproof containers just as soon as they're completely dry. Canning jars that have been rinsed out with boiling

water and dried, of course, make good containers, as do coffee cans and plastic freezer bags. When using a coffee can, first wrap the vegetable pieces in a plastic bag to keep the metal of the can from affecting the flavor of the food.

Pint-size containers or small plastic bags are best for packaging dried vegetables. Try to pack the food tightly but without crushing it. If you're using plastic bags, force out as much air as possible before closing them. By using small bags, several may be packed into a larger jar or coffee can — that way you can use small portions as needed, without exposing the whole container to possible contamination each time it's opened.

Storing foods safely

Store your packaged, dried vegetables in a cool, dark, dry place. The cooler the temperature of the storage area, the longer foods will retain their high quality. However, dried foods can't be stored indefinitely, since they do lose vitamins, flavor, color, and aroma during storage. Your pantry or kitchen cupboards may provide good storage, if the area remains cool. A dry basement can also be a good spot. Dried vegetables can be stored in the freezer, too — but why take up valuable freezer space with foods that will keep at cool, room temperature?

Many dried vegetables will keep up to 12 months. If properly stored. Carrots, onions, and cabbage will spoil more quickly, so use them up within six months.

To be on the safe side, check the packages of dried vegetables from time to time. If you find mold, the food is no longer safe and should be discarded immediately. If you find a little moisture, but no spoilage, heat the dried vegetables for 15 minutes in a 175°F oven; then cool and repackage. If you find much moisture, the vegetables must be put through the entire drying process again. Remember, you must always cool dried foods thoroughly before packaging; if packaged while still warm, they'll sweat and may mold.

HOW TO USE DRIED VEGETABLES

To use dried vegetables, you have to reverse the drying or dehydration process to rehydrate them. This is accomplished in water or other liquid. If you soak dried vegetables before using them, they'll cook much faster. To rehydrate, add two cups of water for each cup of dried vegetables; boiling water will shorten the soaking time. After soaking, the vegetables should regain nearly the same size as when fresh.

Rehydrated vegetables are best used in soups, stews, salads, casseroles, and other combination dishes. See the recipes that follow for some serving suggestions.

BASIC DRYING STEPS

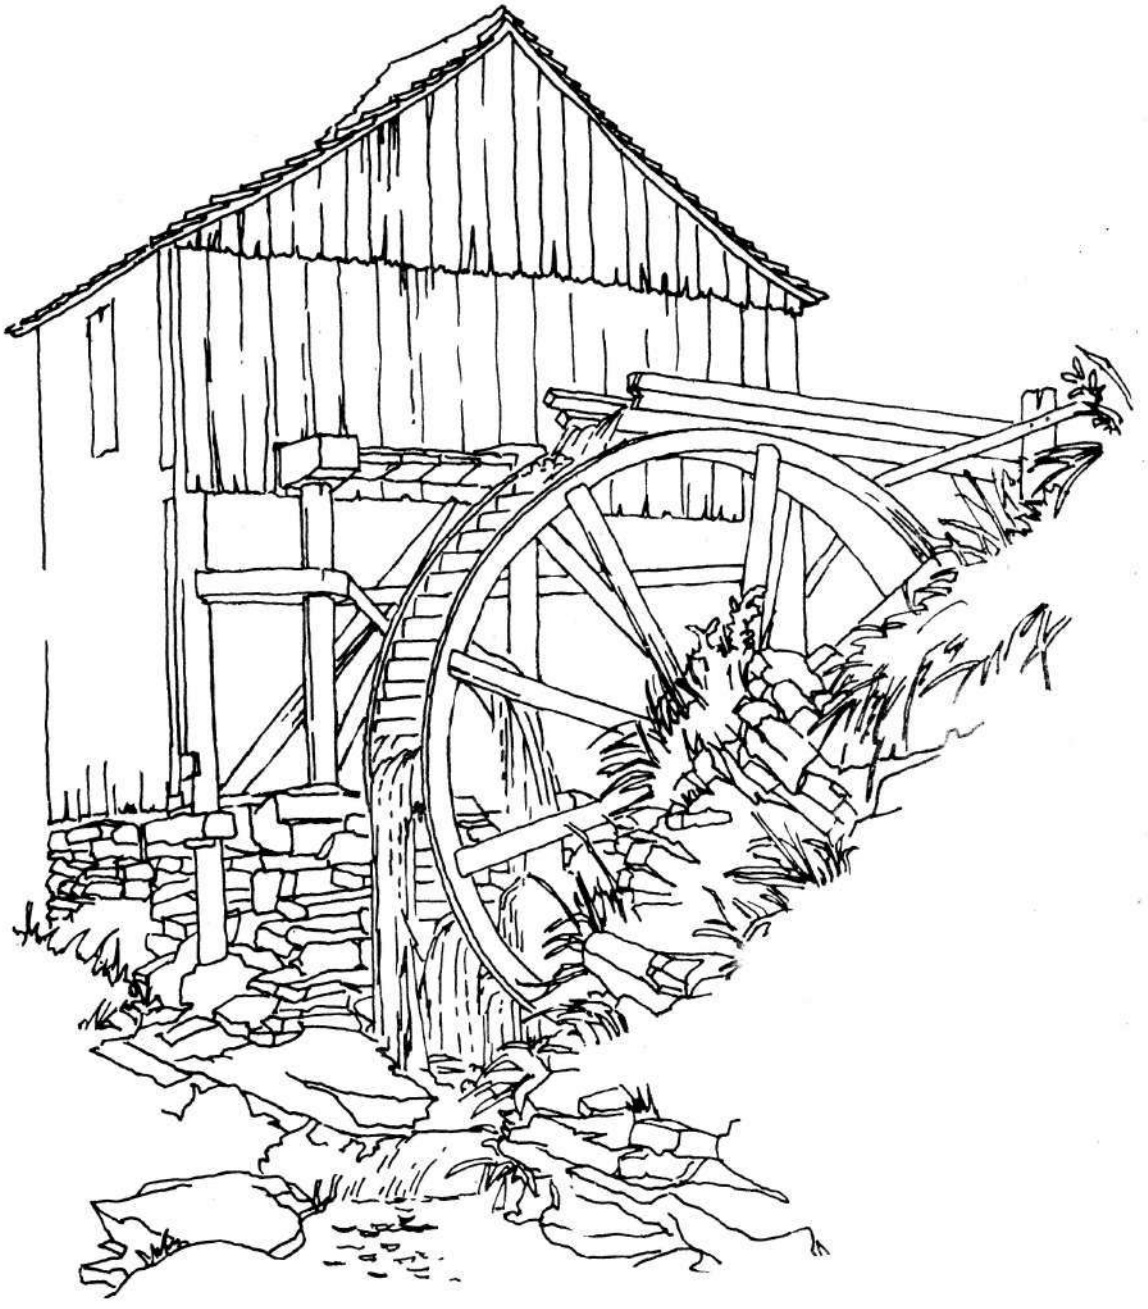
The recipes that follow give you specific directions for drying each vegetable. To prevent problems, keep these basic steps in mind when home drying foods. Remember that only the highest quality vegetables are suitable for drying.

1. Select vegetables that are freshly picked, tender, and just mature enough to eat.
2. Set out all ingredients and equipment. Wash and dry all utensils, counter tops, working surfaces, and your hands.
3. Preheat your conventional oven to 140°F, or follow the manufacturer's directions for your electric dryer or dehydrator, or a convection or microwave oven.
4. Wash the vegetables thoroughly, scrubbing with a brush if necessary, but handling them gently to avoid bruising.
5. Cut, slice, or grate the food according to the recipe directions.
6. Blanch the vegetables in small amounts at a time, according to recipe directions. For steam blanching, fill the blancher with just enough water to cover the bottom, but not to touch the basket or rack. For blanching by boiling, fill the blancher about half full, then begin heating. After blanching, chill the vegetable pieces in ice water for the same amount of time the recipe gives for blanching in boiling water.
7. Drain the chilled vegetables well, blot them dry, then spread them in a single, even layer on cookie sheets or on the racks of an electric dryer. Don't crowd the vegetables on the sheet and don't prepare more vegetables than you can dry at one time.
8. For conventional oven drying, put an oven thermometer toward the back of the tray. Put the tray on the top shelf in a preheated oven, and maintain an oven temperature of 140°F.
9. For box drying, turn on the light bulb for 10 to 15 minutes to preheat the box. Place the tray on top of the box.
10. For convection oven drying, place the racks full of food into a cold oven. Set the temperature at 150°F. Open the oven door 1 to *VA* inches. Set the oven timer to the "stay on" position, or for as long as it will run, resetting as needed.
11. For drying in an electric dryer or dehydrator.

or a microwave or convection oven, follow the manufacturer's directions.

12. For both oven and box drying, check the trays often, and stir the vegetables on the trays, moving the outside pieces to the center. For oven drying, turn the tray from front to back and — if drying more than 1 tray — change the trays from shelf to shelf for even drying. Check the trays more frequently during the last few hours of drying to prevent scorching. For microwave oven drying, follow the manufacturer's directions. Use the lower end of drying times given in the recipes as a guide for doneness when you're using a conventional, microwave, or convection oven. The upper range of drying times is a guide to doneness when you're using an electric dryer or dehydrator.
13. To test for doneness, remove sample pieces, cool, and then follow the recipe directions for testing for doneness. When the vegetables are completely dry, as described in each recipe, remove them from the oven or box and let stand until cooled. Test the vegetables again after cooling. If the food still shows some moisture, return it to the oven or dryer until completely dried.
14. Turn the dried vegetables into a deep container, cover lightly with cheesecloth, and condition, stirring once a day for a week to 10 days.
15. Pack into vapor/moistureproof, airtight containers or double plastic bags and store in a cool, dark, dry place for up to 12 months.
16. To rehydrate, put the vegetables in a pan or bowl, and add just enough boiling water to cover — usually 2 cups of water per cup of dried vegetables, anywhere from 1/2 hour to several hours, depending on the vegetable.
17. Cook vegetables in their soaking water until tender, or drain and add to recipes just as you would fresh vegetables.

How to Sprout Vegetables



Sprouting is one of the easiest ways to grow fresh vegetables for eatings both in and out of season. While mung bean sprouts have long been familiar in Chinese cooking, alfalfa and other sprouts have become equally well-known in recent years. More and more ingenious and health-conscious cooks are adding a variety of sprouts to salads, sandwiches, soups, and other dishes — for both the crunch and the nutrition. Sprouts are bursting with nutrients, and certain vitamins even increase when seeds are sprouted — up to 600 percent.

And sprouts are economical, too — from a single pound of seeds, you can produce from six to eight pounds of sprouts. All you have to do is add a little moisture and a little warmth to the seeds, set them in a dark place, then sit back and watch your garden grow in just a few day's time.

It's fun to have several jars of sprouts going at once, so you'll always have variety as well as a good supply. For example, put a couple of tablespoons of alfalfa seeds in one jar, a cup of wheat or rye berries in another, and a half cup or so of lentils in a third jar. Alfalfa takes about five days to reach just the right stage for eating, but your wheat sprouts will be ready by the end of the second day. It's a fast, easy, and very rewarding way to enjoy vegetables — both the ones you grow yourself and the ones you don't.

BASIC SPROUTING EQUIPMENT

All you need to sprout seeds is a jar, some cheesecloth, plastic mesh, or plastic screen to cover the jar, and a rubber band to hold it in place. But you can also sprout seeds on a tray, on damp towels, in a clay flowerpot saucer, or in a thin layer of soil. You may also want to try the ready-made sprouters that are available in large department stores and health food stores. For example, you can buy mesh trays or sprouting lids made of plastic mesh that fit on standard one-quart canning jars. It's a good idea to try various methods to find ones that are most convenient and work best for you.

BASIC INGREDIENTS

You can sprout all kinds of seeds, legumes, and grains. Try wheat, rye, alfalfa, mung beans, chick peas, soybeans, pumpkin seeds, sesame seeds, or any of the other sprouting seeds, grains, and vegetables suggested in "Directions for Sprouting," later in this chapter. Only one thing is essential — when buying seeds for sprouting, *always* check to be sure you're getting live, untreated seed. Seeds that are intended to grow crops are specially treated to make them resistant to insects and plant diseases — and you shouldn't eat sprouts started from these chemically treated seeds.

You also can't sprout seeds that have been heat-treated, because even relatively low temperatures kill the seeds, leaving them edible but no longer capable of growth. For this reason, if you're growing beans, peas, or other vegetables for sprouting, be sure to use the drying method recommended for this purpose. Seeds dried by blanching, chilling, and heating will not sprout.

The only other ingredient you'll need for sprouting is water. Some experts recommend that you let city water (which may be high in chlorine) sit for a day or two before you use it, in order to let the chlorine dissipate into the air. When sprouting seeds, use lukewarm or room-temperature water, rather than cold or hot.

BASIC SPROUTING TECHNIQUES

Sprouting can be done in a jar, in a tray, on a towel, in a clay saucer, or in a thin layer of soil. Each method works best for certain kinds of seeds, as you'll see from the following descriptions.

Although the basic steps are quite similar from one method to the next, the times and temperatures for sprouting will vary due to temperature and humidity variations in your home. That means you've got to check sprouts frequently. After your first couple of batches, you'll have a good idea how long it takes to produce the flavor you prefer in sprouts. Many sprouters also like to save the water drained from sprouts for use in soups or sauces, or for watering houseplants.

Jar sprouting

This method works best for small seeds, such as alfalfa, clover or radish.

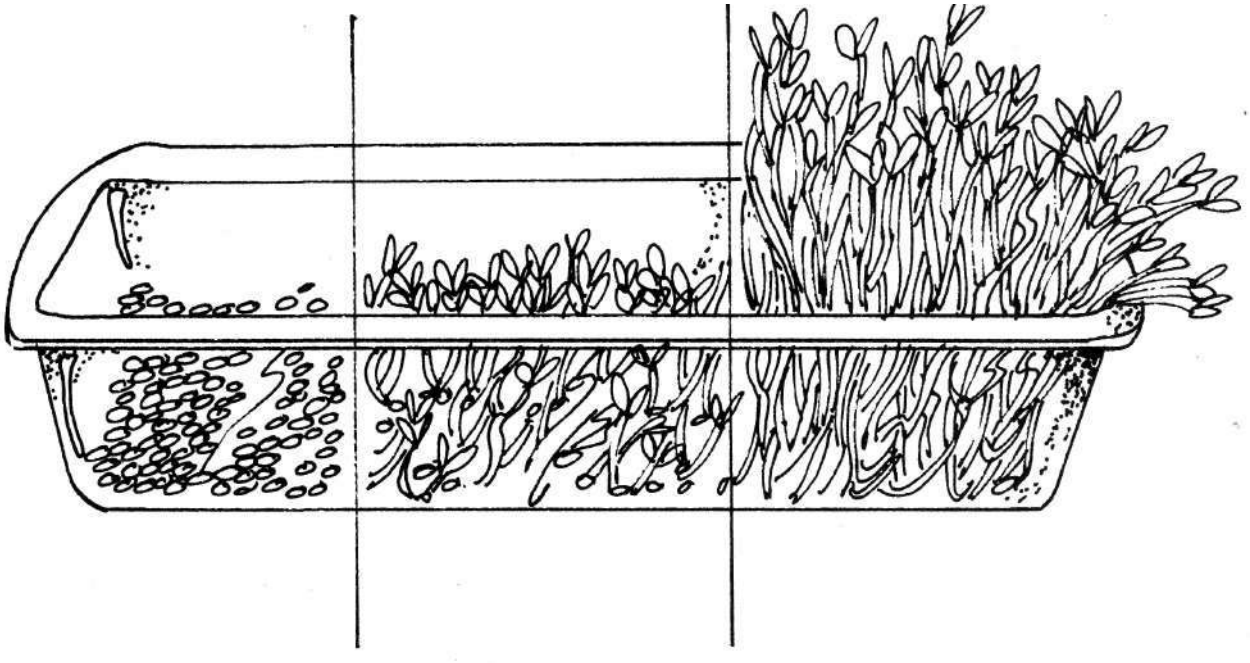
1. Rinse the seeds in lukewarm water.
2. Put the seeds in a jar, then add 3 times as much water as you have sprouts. Cover with a plastic mesh lid, cheesecloth, or nylon net, then fasten with a rubber band or canning jar-screw band. (You won't need to remove the mesh covering until the sprouts are ready to harvest.) Set aside and soak for the time given in the recipe.
3. At the end of the soaking time, drain off the water (through the mesh covering).
4. Rinse the seeds with lukewarm water and drain.
5. Set the jar in a warm (60°F), dark place, at an angle so that the sprouts can drain.

6. Rinse and drain the sprouts twice a day, or as the recipe directs. (In hot, dry weather, rinse them 3 to 4 times a day.) Turn the jar gently as you rinse and drain so that the sprouts won't break off. If the weather or your kitchen is very humid, move the sprouts to a dry place, such as near the stove or wrapped in a towel (to keep out light) near a sunny window. Too much humidity will prevent sprouting. Temperatures above 80°F can also prevent sprouting.
7. On about the fourth day, move the jar of sprouts into the sunlight so that chlorophyll can develop and turn the leaves green. Continue to rinse and drain.
8. Move the sprouts from the jar to a strainer, and rinse well to remove the hulls, if desired. Hulls can shorten storage life of sprouts, but they also add flavor.
9. Use sprouts immediately in salads, sandwiches, or as the recipe suggests. To store, put in plastic bags and refrigerate.
10. Wash and dry all equipment and put away for next use.

Tray sprouting

This method works best for seeds such as mung bean, chia, and lettuce.

1. Rinse the seeds in lukewarm water.
2. Put the seeds in a jar, then add 3 times as much water as you have sprouts. Cover with a plastic mesh lid, cheesecloth or nylon net, then fasten with a rubber band or canning jar screw band. Set aside and soak for the time given in the recipe.
3. At the end of the soaking time, rinse the seeds and spread in a tray. (The tray can be a wooden box with a plastic, nylon, or wire mesh bottom, or a perforated plastic tray.)
4. Cover the tray with plastic wrap and then with newspaper or another light-blocking cover. Keep one end of the tray bottom propped up so the sprouts can drain. Set the tray in warm (70°F), dark place.
5. Rinse and drain sprouts twice a day. (In hot, dry weather, rinse them 3 or 4 times a day.) Rinse gently (so the sprouts won't break) under a faucet (not full-force), the sprinkler attachment of your sink, or by lowering the tray slightly into a sink of lukewarm water. Cover the tray again after each rinsing.
6. On about the fourth day, move the tray of sprouts into sunlight so chlorophyll can develop and turn the leaves green. Continue to rinse and drain.
7. Move the sprouts from the tray to a strainer, and rinse well to remove the hulls, if desired.



Tray sprouting gives you sprouts from seeds in four days; it's the best method to use for sprouting seeds like mung bean, chia, and lettuce.

Hulls can shorten storage life of sprouts, but they also add flavor.
8. Use sprouts immediately in salads, sandwiches, or as the recipe suggests. To store, put in plastic bags and refrigerate.
9. Wash and dry all equipment and put away for next use.

Towel sprouting

This method works best for larger grains and seeds.

1. Soak the seeds in a jar in 3 times as much water as you have seeds for time given in recipe, then rinse and arrange on a damp towel.
2. Cover with another damp towel, and wrap in plastic wrap or place inside a plastic bag.
3. Set the bag of towels aside, in a warm (70'* F), dark place.
4. Dampen the towels daily by misting them with water.
5. If the seeds haven't sprouted after 2 days, change the towels to prevent spoilage.
6. On about the fourth day, remove the top towel and move the sprouts into the sunlight so that chlorophyll can develop and turn the leaves green. Mist as needed.
7. Move the sprouts from the towel to a strainer, and rinse well to remove the hulls, if desired. Hulls can shorten the storage life of sprouts, but they also add flavor.
8. Use sprouts immediately in salads, sandwiches, or as the recipe suggests. To store, put in plastic bags and refrigerate.
9. Wash and dry all equipment and put away for next use.

Clay saucer sprouting

This method works best for gelatinous seeds that are difficult to rinse in jars.

1. Use a clean, unglazed clay flowerpot saucer.
2. Put equal amounts of seeds and water into the saucer.
3. Set the saucer in a larger pan and pour water into the pan to within 1/2 inch of top of saucer.
4. Cover with a plate and set aside in warm (70°F), dark place.
5. Check the seeds daily, misting them if they become dry, or removing the plate cover for a day if they're too wet.
6. On about the fourth day, move the sprouts into the sunlight so the leaves turn green. Mist as needed.
7. Move the sprouts from the saucer to a strainer, and rinse well to remove the hulls, if desired. Hulls can shorten storage life of sprouts, but they also add flavor.
8. Use sprouts immediately in salads, sandwiches, or as the recipe suggests. To store, put in plastic bags and refrigerate.
9. Wash and dry all equipment and put away for next use.

Soil sprouting

This method works best for sprouting tiny greens for salads or for wheat, rye, or triticale grasses.

1. Spread a 1-inch layer of equal parts of moist peat moss and top soil over the bottom of a box.
2. Soak the seeds in 3 times as much water as you have seeds and soak for the time given in the recipe; rinse and jar sprout for 16 to 24 hours.
3. Spread the seeds over the soil in the box.
4. Cover with plastic wrap and then newspaper or black plastic (to keep out light).
5. When the sprouts are \ inch tall, remove the cover and move them into sunlight so that chlorophyll can develop and turn the leaves green. Water as needed.
6. When greens are the desired height — about 2 to 3 inches — pull or cut them, wash them well, and use them in salads. To store, put in plastic bag and refrigerate.
7. Wash and dry all equipment and put away for next use.

DIRECTIONS FOR SPROUTING VEGETABLES

Try sprouting just about any seed, grain, or legume for some of the most delicious, nutritious, and economical foods to be found anywhere. Sprouts can be added to many dishes besides salads, soups, and sandwiches. They're delicious baked into whole-grain breads or muffins, blended into juices, or added to granola or yogurt. You can sprinkle them on casseroles and on meat, fish, or fowl dishes of all ^ kinds. You can even top sprouts with tomato sauce and eat them like spaghetti.

The instructions below will give you some idea of the yield you can expect from sprouting various seeds and grains, but yields can vary considerably, depending on the size of the seeds, the temperature, and the length of the sprouts when you harvest them. Generally, small seeds—like chia — yield about eight times their original bulk in sprouts; large seeds — like corn — yield about three times their

original bulk. Experiment with these wonder foods — you'll create some family favorites of your own.

Aduki (azuki) or pichi beans

Use about 1/2 cup seeds in a 1-quart jar, which will yield about2 cups of sprouts. Soak for 12 hours. Rinse 3 to 4 times daily for 3 to 4 days. Harvest when the sprouts are 1/2 to 11/2 inches long. Good in salads or casseroles, or stir-fried.

Alfalfa

Use about 21/2 tablespoons seeds in a quart jar, or sprout on trays. This will yield about 1 quart of sprouts. The yield will be 11/2 cups for each 1/4 cup sprouted, and the sprouts will be very short — only about 1/8 inch long. Soak for 8 hours. Rinse 2 to 3 times daily for 4 to 6 days. Move into sunlight to green, then harvest when the sprouts are 11/2 to 2 inches long. Use in salads, sandwiches, omelets, or as garnish. To use in baked goods, harvest sprouts after just 2 days.

Barley

Use 1 to 11/2cups seeds in a 1-quart jar, which will yield about 1 quart of sprouts. Soak for 12 hours. Rinse 2 to 3 times daily for 2 to 3 days. The sprouts will be the length of the seed. Use in salads, casseroles, and breads.

Beans, dry

Use 3/4 cup mature beans in a 1-quart jar, which will yield about 1 quart of sprouts. Soak for 14 hours. Rinse 3 or 4 times daily for 3 or 4 days. Harvest when sprouts are 1 to *11/2* inches long. Use in casseroles, soups, or dips, or steam them.

Beans, mung

Use 1/3 cup in a 1-quart jar, or tray sprout, which will yield abouti cup of sprouts. Soak for16 hours. Rinse 3 to 4 times daily for 3 to 5 days. Harvest when the sprouts are 1 to 3 inches long. Use in oriental dishes, salads, sandwiches, omelets, or stir-fry.

Cabbage

Use 3 tablespoons seeds in a 1-quart jar, which will yield about 1 quart of sprouts. Soak for 10 hours. Rinse 2 to 3 times daily for 3 to 5 days. Move into sunlight to green, then harvest when the sprouts are 1 to 11/2 inches long. Use in salads and sandwiches.

Chia

Use 1/4, cup seeds in a clay saucer or tray, which will yield about 2 cups of sprouts. There's no need to soak or rinse and drain; just mist the seeds regularly to keep them moist. After 3 to 5 days, move into sunlight to green. Harvest when the sprouts are 1 to 11/2 inches long. Use in salads, sandwiches, casseroles, and as a garnish.

Chick peas

Use 1 cup in a jar, or tray sprout, which will yield about3 cups of sprouts. Soak for 14 hours. Rinse 3 to 4 times daily for 3 to 4 days. Harvest when sprouts are 1/2 inch long. Use in casseroles, soups, salads, steamed, or as a base for dips.

Chinese cabbage

Use 1 tablespoon seeds in a 1-quart jar, or tray sprout, which will yield about 2 cups of sprouts. Soak for 8 hours. Rinse 2 to 3 times daily for 4 to 5 days. Move into sunlight to green, then harvest when the sprouts are 1 to *11/2* inches long. Use in salads, sandwiches, and juices.

Corn

Use 1 cup kernels in a 1-quart jar, or tray sprout, which will yield about 3 cups of sprouts. Soak for 20 hours. Rinse 3 times daily for 2 to 4 days. Harvest when the sprouts are 1/2 inch long. Use in casseroles, soups, and tortillas, or bake, steam, or stir-fry.

Clover

Use 1 tablespoon seeds in a 1-quart jar, or tray sprout, which will yield about 2 cups of sprouts. Soak for 8 hours. Rinse 2 to 3 times daily for 4 to 6 days. Move the jar into sunlight to green, then harvest the sprouts when they're 11/2 to 2 inches long. Use in salads, sandwiches, and juices. To use in baked goods, harvest the sprouts after just 2 days.

Cress

Use 1 tablespoon of seeds in a clay saucer or tray, which will yield about 11/2 cups of sprouts. There's no need to soak or rinse and drain; just mist with water 3 times daily for 3 to 5 days. Move into sunlight to green, then harvest when the sprouts are 1 to 11/2 inches long. Use as a spice (very peppery flavor), in salads, sandwiches, or baked goods.

Dili

Use 1/4 cup in a 1-quart jar, or tray sprout, which will yield about2cupsofsprouts. Soak for 8 hours. Rinse 3 times daily for 3 to 5 days. Move Into sunlight to green, then harvest when the sprouts are 1 to 11/2 inches long. Use in salads, sandwiches, and juices.

Fenugreek

Use 1/4 cup In a 1-quart jar, or tray sprout, which will yield about 1 quart of sprouts. Soak for 10 hours. Rinse 2 to 3 times dally for 3 to 5 days. Mist with water if tray sprouting, to keep damp. Harvest when 1/2 to 2 Inches long. Use in salads and sandwiches.

Flax

Use 1/4 cup in a clay saucer, or tray sprout, which will yield about 1 cup of sprouts. Without soaking or rinsing the seeds, mist with water 3 times daily for 3 to 5 days. Move into sunlight to green, then harvest when the sprouts are 1 to 11/2 inches long. Use in salads or juices.

Lentils

Use 3/4 cup in a 1-quart jar, or tray sprout, which will yield about 6 cups of sprouts. Soak for 8 to 10 hours. Rinse 2 to 3 times daily for 2 to 3 days. Harvest when the sprouts are 1/4 to 1/2 inch long. Use in salads, sauces, dips, juices, soups, or casseroles.

Lettuce

Use 3 tablespoons in a 1-quart jar, or tray sprout, which will yield about 2 cups of sprouts. Soak for 8 hours. Rinse 2 to 3 times daily for 4 to 5 days. Move into sunlight to green. Harvest when the sprouts are 1 to 11/2 inches long. Use as a garnish (flavor is strong).

Millet

Use 11/2 cups in a 1-quart jar, or tray sprout, which will yield about 2 cups of sprouts. Soak seeds for 8 hours. Rinse 3 times daily for 4 to 5 days. Harvest when sprouts are 1/4 inch long. Use in salads, soups, baked goods, casseroles, and juices.

Mustard

Use 3 tablespoons in a 1-quart jar, or tray sprout, which will yield about 1 quart of sprouts. Do not soak. Rinse 2 to 3 times daily for 4 to 5 days. Move Into sunlight to green, then harvest when the sprouts are 1 to 11/2 inches long. Use in salads, juices, or as garnish.

Oats

Use 11/2 cups in a 1-quart jar or sprout on towels, which will yield about 2 to 3 cups of sprouts. Soak for 1 hour. Rinse once or twice daily for 3 days. The sprouts will be the length of the seed. Use in salads, granola, and baked goods.

Peas

Use 1/2 cup black-eyed or shelling in a 1-quart jar, or tray sprout, which will yield about 1 cup of sprouts. Soak for 12 hours. Rinse 2 to 3 times daily for 3 days. Harvest when sprouts are 1/4 to 1/2 inch long. Use in salads, soups, omelets, and casseroles.

Peanuts

Use 11/2 cups in a 1-quart jar, or tray sprout, which will yield about 1 quart of sprouts. Soak for 14 hours. Rinse 2 to 3 times daily for 3 to 4 days. Harvest when sprouts are 1/4 to 1 inch long. Use In soups, steam, or stir-fry.

Pumpkin

Use 11/2 cups in a 1-quart jar, or tray sprout, which will yield about 3 cups of sprouts. Soak for 10 hours. Rinse twice daily for 2 to 3 days. Harvest when the sprouts are 1 to 11/2 Inches long; pick off hulls and rinse. Use in sauces, dips, and baked goods.

Radish

Use 3 tablespoons in a 1-quart jar, or tray sprout, which will yield about 1 quart of sprouts. Soak for 8 hours. Rinse 2 to 3 times daily for 4 to 5 days. Move into sunlight to green, then harvest when the sprouts are 1 to 2 inches long. Use in salads, sandwiches, and juices.

Rye

Use 1 cup in a 1-quart jar, or tray sprout, which will yield about 2 to 3 cups of sprouts. Soak for 12 hours. Rinse twice daily for 2 to 3 days. Sprouts will be the length of the seeds. Use in granola, salads, baked goods.

Sesame

Use 1 cup in a 1-quart jar, or tray sprout, which will yield about 2 cups of sprouts. Soak for 8 to 10 hours. Rinse 3 to 4 times daily for 3 days. The sprouts will be the length of the seed. Use in granola, baked goods.

Soybeans

Use % cup in a 1-quart jar, or tray sprout,.which will yield about 1 quart of sprouts. Soak for 12 to 24 hours, changing the soaking water once. Rinse 3 to 4 times daily for 3 to 4 days. Harvest when sprouts are 1/2 to 2 inches long. Use in oriental dishes, salads, casseroles, baked goods, or steam.

Squash

Use 1 cup in a 1-quart jar, or tray sprout, which will yield about 3 cups of sprouts. Soak for 10 hours. Rinse twice dally for 2 or 3 days. Harvest when the sprouts are 1 to 11/2 inches long; pick off hulls and rinse. Use in sauces, dips, and baked goods.

Sunflower^ hulled

Use 1 cup in a 1-quart jar, which will yield about 3 cups of sprouts. Soak for 10 hours. Rinse 2 to 3 times daily for 2 to 5 days. Harvest when the sprouts are 1 to 11/2 inches long. Use In salads, sauces, and dips.

Triticale

Use 1 cup in a 1-quart jar, which will yield about 2 to 3 cups of sprouts. Soak for 12 hours. Rinse twice daily for 2 to 3 days. The sprouts will be the length of the seed. Use in granola, salads, soups, and baked goods.

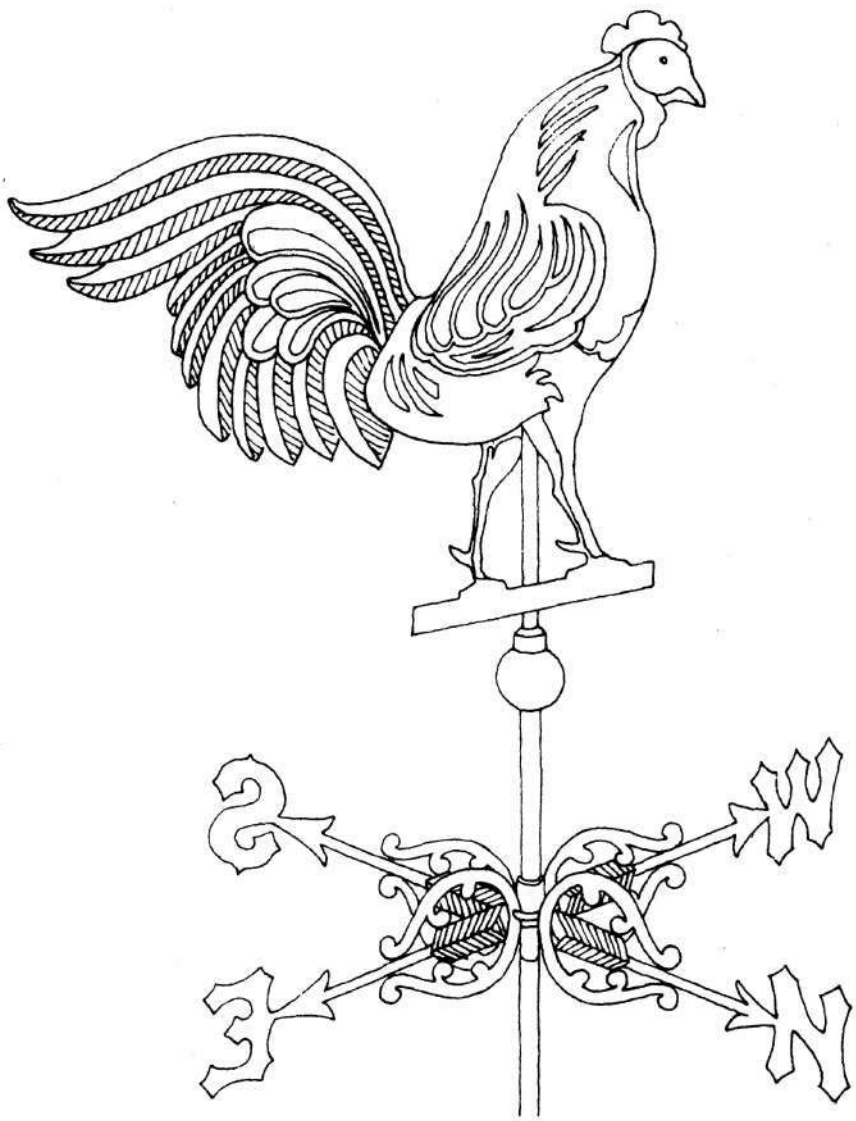
Turnip

Use 3 tablespoons in a 1-quart jar, which will yield about 1 quart of sprouts. Soak for 12 hours. Rinse twice daily for 3 to 4 days. Move into sunlight to green, then harvest when the sprouts are 1 to 11/2 inches long. Use in salads and sandwiches.

Wheat

Use 1 cup in a 1-quart jar, or tray sprout; which will yield about 4 cups of sprouts. Soak for 12 hours. Rinse twice daily for 2 to 3 days. The sprouts will be the length of the seed. Use in granola, salads, soups, baked goods.

How to Store and Use Herbs



Herbs are the secret ingredient in many a fine recipe — from the most delicate gourmet dish to the heartiest of folk fare. Yet herbs are also among the easiest vegetables to grow, to use fresh, or to store for the winter. If you live in a mild climate, you can grow herbs year-round in your garden, in window pots, along walkways, or near doorways or patios. And if you live where winters get too cold for outdoor gardening, you can grow little pots of basil or chives indoors, and freeze, dry, or salt the rest of your herb crop. Dried herbs will keep for up to a year; frozen herbs will keep fresh for several months if properly wrapped and stored.

Herbs are popular in cooking not only for the way they enhance the flavor of many foods, but for the fact that they add no calories. If you're on a special diet, herbs can add zest to those low-cal or no-salt recipes. For example, when cooking potatoes or rice, add a pinch of rosemary instead of salt to the cooking water to add a special flavor.

GROWING HERBS: ROBUST AND FINE

Some herbs are used only in food preparation (robust herbs); and others can be eaten raw as well (fine herbs). Among the most popular herbs are basil, chives, dill, garlic, marjoram, oregano, parsley, rosemary, sage, sweet marjoram, and thyme. Grow them where you can enjoy their beauty and fragrance, as well as harvest the leaves at just the peak moment for use in your favorite foods. Detailed information on growing these and other herbs is given in Parts 1 and 2.

USING FRESH HERBS

You can use fresh herbs throughout the growing season. First, gently remove a few leaves at a time, or pinch or cut off sprigs to be chopped and added to your soups, salads, and sauces. For immediate use, rinse the herbs, pat them dry, and then chop finely. If you can't use fresh herbs at once, wrap them in a damp paper towel, then in plastic wrap or a plastic bag, and refrigerate. Fresh herbs can be kept refrigerated for a few hours or up to a day or two — but no longer than that.

Fresh herbs are wonderful in any recipe that calls for herbs. However, if your recipe specifies a dried herb, you can substitute fresh by using three to four times more finely chopped fresh leaves — one teaspoon of fresh herbs is equal to 1/4 teaspoon of dried. Fresh herbs also make beautiful garnishes. Save a perfect sprig to give the finishing touch to vegetables, salads, drinks, fish, meats, casseroles, and sandwiches.

HARVESTING HERBS FOR STORAGE

Herbs can be frozen, dried, or salted for use during the fall, winter, and spring. Depending on the method you'll be using, you can cut whole stalks, remove just the leaves, or pinch off sprigs for your herbs. The dried seeds of some herbs — anise, caraway, coriander, dill, fennel, and sesame — are also used for flavorings, but most herbs are grown for their leaves.

You should harvest herbs to be stored when the flowers of the plant are just beginning to open; this is the moment when flavor is at its peak. Cut the plants on a dry, sunny morning—after the dew has dried, but before the sun gets too hot. The leaves you want are the young, tender, pungent ones growing at the top six inches of the plant. Strip off the tough, lower leaves and remove the flower clusters. Rinse the herbs with cold water to remove dirt and dust, then blot them dry with paper towels.

If you're growing herbs for their seeds, harvest the seeds as soon as the heads turn brown, but before they ripen completely and begin to fall off. Harvest the seeds on a warm, dry day, and then dry them, as detailed below. Seeds are dried in their pods, husks, or coverings. You remove these coverings by winnowing — rubbing a few seeds at a time between your palms to loosen the pod or husk, which will then fall away. Herb seeds should not be frozen or salted.

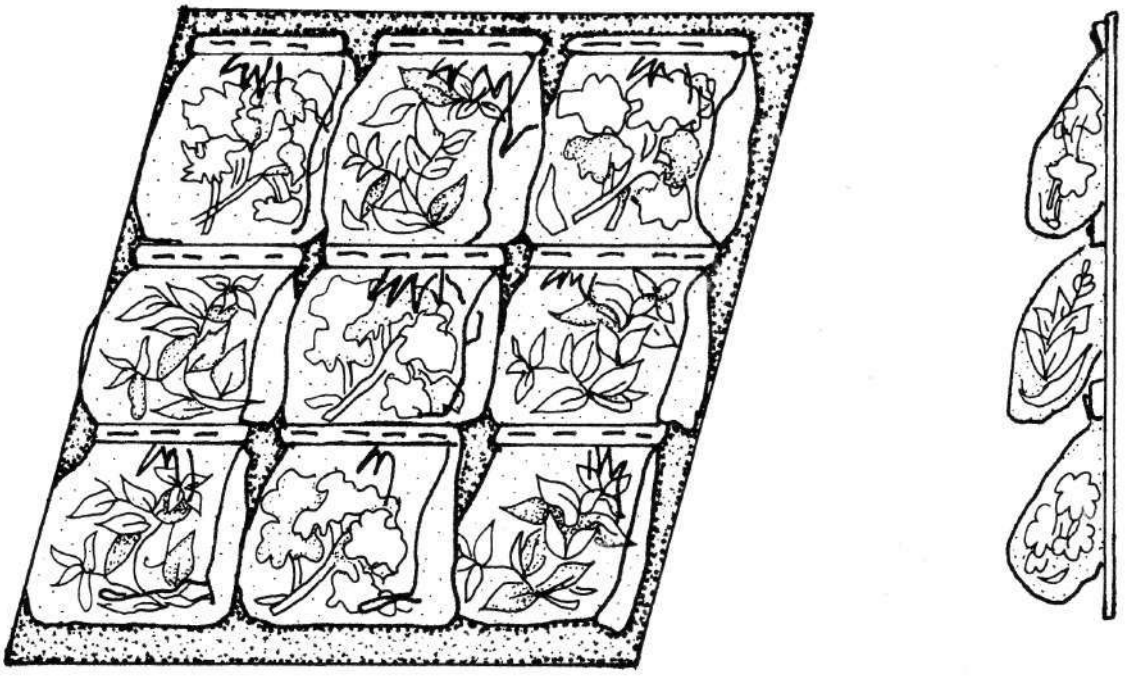
HOW TO FREEZE HERBS

Freezing is a quick way to preserve herbs that will be used in cooked dishes. Since herbs become dark and limp during freezing, they can't be used as garnishes — but their flavor remains just as good as fresh. You can chop herbs before freezing, or freeze sprigs and then just snip them, right from the freezer, into the food you're cooking.

Frozen herbs will keep for several months. If you want to store herbs for longer periods, dry them instead.

To freeze herbs, follow these step-by-step procedures:

1. Have ready a knife or scissors, paper towels, plastic bags, freezer wrap or boilable pouches, cardboard, freezer container or envelope, and labels.
2. Pick fresh, perfect herb sprigs or leaves. Wash them well, then drain and pat them dry with paper towels.
3. Pack recipe-size amounts in small plastic bags or packets made from plastic wrap, freezer



Freeze small amounts of herbs in individual plastic packets and staple them to a piece of cardboard. Label the packets and seal well.

paper or foil, or pack in boilable pouches. Seal well.

4. Staple these individual packets to a piece of cardboard, label the cardboard, and then freeze. Or pack several packets in a freezer container, large envelope, or plastic bag. Seal, label, and freeze.
5. For bouquet garni: Tie together several sprigs of different herbs — parsley, bay leaf, and thyme, for example — and pack as above. When you're ready to use it, add the whole bouquet to the recipe.

HOW TO DRY HERBS

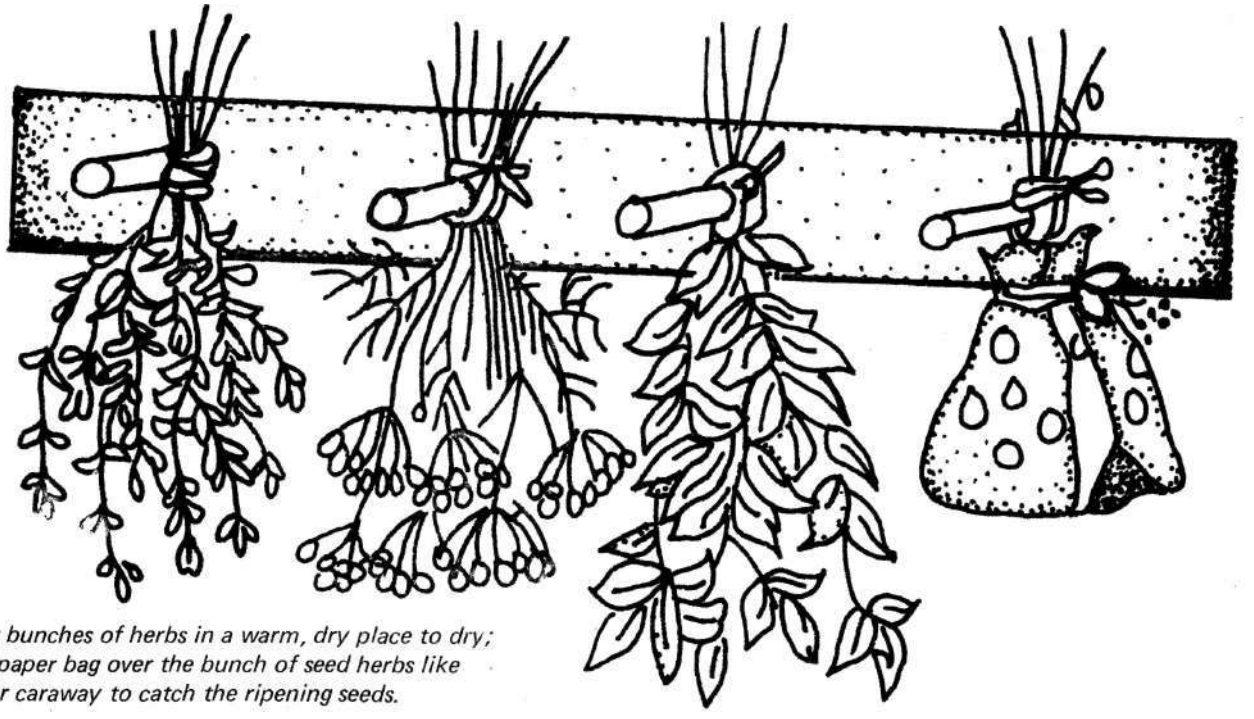
Herbs need no pretreatment before drying, just careful selection and gentle harvesting. Always choose the tender, aromatic leaves growing on the upper six inches of the plant. Herbs may be air-dried in paper bags or dried in your kitchen oven. Herbs should never be dried in the sun because direct sunlight destroys their natural aroma.

For perfect dried herbs, follow these step-by-step procedures:

1. Have ready paper towels, a knife or scissors, string, plastic wrap, cookie sheets, racks or trays and wire mesh or cloth, or brown paper bags.
2. For herb leaves, choose herbs that are just about to blossom. Make sure the herbs are tender and well-colored, with perfect leaves and no bugs. Cut off the top two-thirds of the plant. Pick early in the morning, if possible. For herb seeds, choose seeds that are fully developed and mature.
3. Wash off any dust or dirt from the leaves. Shake them gently and pat dry with paper towels.
4. Dry in bags; on trays; or in a conventional, microwave, or convection oven, as explained below.

Bag drying herbs

1. Gather 6 to 8 stalks and put them in a large brown paper bag to prevent their exposure to light. Hold the ends of the stalks at the top opening of the bag, then tie the bag's top around the stalks with a string. The leaves mustn't touch the sides of the bag, or they may stick to the paper and dry incompletely. Repeat for desired quantity of herbs.
2. Punch a few holes in the bottom and sides of each bag for ventilation, and label each bag.
3. Hang the bags by the string from hooks or hangers in an attic, covered porch, or any other



Hang bunches of herbs in a warm, dry place to dry; tie a paper bag over the bunch of seed herbs like dill or caraway to catch the ripening seeds.

warm, dry, well-ventilated spot away from direct sun.

4. Check the temperature of the area before and during drying to be sure it doesn't rise above 100°F. Herbs will lose their flavorful oils if air-dried at temperatures above 100°F.
5. If you're drying herbs outdoors, be sure to bring them in at night, so they don't pick up moisture from the night air,
6. You'll know the herbs are completely dry when the leaves fall from the stalks and can easily be crumbled between your fingers. You can strip the leaves from the stalks to crush or bottle whole, or just leave them in the paper bags until you're ready to use them.
7. If the leaves haven't dried evenly, strip them from the stalks and spread them in a single, even layer on a cookie sheet. Dry in a 200°F oven for 30 minutes, or until crumbly.
8. Store the dried whole leaves in labeled, airtight containers. In a dark, cool, dry place.

Tray drying herbs

1. Remove the leaves from the stems of the plant and place them on a cloth-covered rack or mesh screen.
2. Place the racks in a warm, dry, well-ventilated room away from direct sun.
3. Stir the leaves from time to time to be sure they dry evenly.
4. When the leaves crumble easily, they're dry.
5. Store the dried whole leaves in labeled, airtight containers, in a dark, cool, dry, place.

Drying herbs in a conventional oven

1. Remove the leaves from the stalks of the plant, and arrange them in a single, even layer on cookie sheets, racks, or trays. Use drying trays 11/2 to 2 inches smaller all around than the , inside of your oven, so air can circulate freely around them.
2. Set the trays in the oven, with at least *V/2* inches between the layers of drying trays.
3. Dry the leaves in a 120°F oven or In a drying box until the leaves will crumble easily between your fingers. Prop the oven door open slightly for ventilation and to keep the oven temperature from rising too high. The herbs will dry in 2 to 4 hours.
4. Store the dried leaves whole in labeled, airtight containers, in a dark, cool, dry, place.

Drying herbs in a microwave oven

1. Place 3 or 4 stalks between several thicknesses of paper towels on a drying rack or cookie sheet.
2. Set the sheet In the oven.
3. Dry at medium power for 2 or 3 minutes, or until the leaves crumble easily. If the herbs still

aren't dry, return the leaves to the oven at the same heat for an additional 30 seconds.
4. Store the dried whole leaves in labeled, airtight containers, in a dark, cool, dry place.

Drying herbs in a convection oven

1. Remove the leaves from the stalks, and arrange them in a single, even layer on cookie sheets, racks, or trays.
2. Set the racks in a cold convection oven.
3. Set the oven temperature setting below the "warm" or 150°F setting. Use an oven thermometer to be sure the temperature inside the oven doesn't exceed 100°F.
4. Dry the leaves until they are brittle.
5. Store the whole leaves in labeled, airtight containers, in a dark, cool, dry place.

HOW TO DRY HERB SEEDS

Herb seeds can be dried by the same method used to dry leaves. After drying, remove the outer covering from dried seeds. Just rub a few seeds at a time between the palms of your hands, and then shake them gently to let the outer seed covering fall away. Store seeds in labeled, airtight containers in a dark, cool, dry place.

STORING DRIED HERBS

As soon as the leaves are dry, store herbs whole in labeled, airtight containers in a dark, cool, dry place. Coffee cans lined with a plastic bag or tinted glass containers are best, since they keep out light. Don't crush the leaves until you're ready to use them, because whole herbs hold their flavor the longest. During the first week after drying, check the herbs to be sure they're completely dry. If you notice any moisture at all, dry the leaves a little longer.

You can keep dried herbs up to a year, if they're stored properly in a dark, cool, dry place. If your storage area is too warm, the leaves will begin to lose flavor. If the area is too moist, the herbs may cake, change color, or spoil. Always remember to close the containers tightly after each use to prevent the loss of the volatile oils which are what make herbs so flavorful.

If you want to verify the freshness of herbs you've been storing for some time, rub a leaf between your palms. If the herb is still potent, strong aroma will be released. If there's little or no fragrance released, the flavor has faded, and you'll need to put up a fresh supply.

COOKING WITH DRIED HERBS

When using dried herbs, first crush or chop the leaves to release the flavor and aroma. Use herbs singly or combine one particularly strong herb with several other milder ones. You can also make a bouquet garni by tying together or placing in a cheesecloth bag bunches of herbs such as celery leaves, parsley, onion, and thyme. Or, mix three or more herbs to make fine herbs. The most familiar combinations for fine herbs are chervil, chives, and parsley; and basil, sage, and savory.

You'll get the most from herbs in cooking if you add them at the right time. For example, when preparing stews or soups that must cook for several hours, add herbs during the last half hour of cooking time. The flavor and aroma of herbs can be lost if they cook too long. In foods that cook quickly, add the herbs immediately.

You'll get best results if you add herbs to the liquid portion of your recipe before mixing it with the rest of the ingredients. Moistening the herbs first with a little water, oil, or other suitable liquid and allowing them to stand for 10 minutes will bring out the flavor even more.

When substituting dried herbs for fresh in a recipe, use 1/4 amount specified. One teaspoon fresh herbs equals 1/4, teaspoon dried.

SALTING HERBS FOR STORAGE

You can salt away some herbs to preserve them for future use. Use pure granulated or pickling salt, not iodized table salt. This method is most popular for basil, but it can be used for other herb leaves too.

To salt herbs down, follow these step-by-step procedures:

1. Have ready pickling salt, paper towels, and jars or other containers with tight-fitting lids, and labels.
2. Choose perfect, fresh basil or other herb leaves. Wash and drain, then pat them completely dry with paper towels.
3. Pour a layer of salt into the container and arrange a layer of leaves on top.
4. Pour in another layer of salt, then add a layer of leaves. Repeat until the container is full, ending with a layer of salt. Press down firmly.
5. Cover the container tightly, label, and store it in a dark, cool, dry place. Use salted herbs just as you would fresh herbs, but be sure to rinse thoroughly to remove the salt before adding them to food.

SPECIAL TREATS WITH HERBS

A little herb goes a long way in cooking, so you'll want to find other uses for the bounty of your herb garden. Herb vinegars, herb teas, herb butters, and herb jellies are easy to make and delicious to use.

Herb vinegars

Adding sprigs of fresh herbs to vinegar provides wonderful flavor. Pretty bottles of your own herb vinegars make wonderful gifts, too. You can use any herb you like, or any combination you prefer. Tarragon in white wine vinegar, basil and garlic in red wine vinegar, and mint or savory in white or cider vinegar are just a few examples.

1. Have ready measuring cups, glass mixing bowl, saucepan, strainer, jars or bottles, and labels.
2. Select perfect, fresh herb leaves. (You'll also want perfect sprigs to go in the bottles, but don't harvest these until after you've let the leaves steep in vinegar for a few days.)
3. For each pint of herb vinegar, lightly crush about y2 cup of fresh herb leaves in large glass mixing bowl. Add 1 pint white, cider, or wine vinegar. Cover and set aside for 3 to 5 days.
4. Now gather as many perfect herb sprigs as you'll have bottles of vinegar. Wash them.
5. Wash the bottles well, rinse, and then sterilize them by simmering in water to cover for about 5 minutes.
6. Strain the vinegar and discard the herbs. Heat the vinegar to boiling.
7. Pour the hot vinegar into hot bottles or jars. Add a sprig of fresh herb to each bottle or jar.
8. Close the bottles with corks, lids, or other airtight seals. Label and store in a dark, cool, dry place.

Herb teas

Fresh herbs have long been favorites for use in infusions, or teas. You can use almost any dried herb you like, but you'll have to test and taste to determine how strong you like it. Mint, rosemary, marjoram, and thyme are favorites for tea, but why not experiment with some others, too? Use about one teaspoon of dried herb (or a combination of herbs) for each teacup (six ounces) of boiling water. Put the herbs directly into the teapot and add the boiling water, or put the herbs in a tea ball. Let steep for five to 10 minutes. Don't add milk or cream. Sweeten, if desired, with honey or sugar.

Herb butters

Herb-flavored butters make marvelous toppings for bread, vegetables, meats, and seafoods. Use anise or oregano butter on your own sweet corn; basil butter on broiled tomato slices; tarragon butter on broiled fish filets; garlic and oregano butter on French bread slices; and marjoram butter on fresh green peas.

You can chop or crush fresh or dried herb leaves to cream with softened butter, or mix the leaves and butter together in a blender or food processor. Use about two tablespoons dried or 1/2 cup fresh herbs for each stick 1/2 cup) of butter. Store herb butters tightly covered in the refrigerator. Use in a few days.

INTRODUCTION 1

DEFOLIATORS 5

Family: Lymantriidae

Calliteara pudibunda (Linnaeus) - Pale tussock moth 6
Lymantria dispar (Linnaeus) - Gypsy moth 8
Lymantria monacha (Linnaeus) - Nun moth 10

Family: Tortricidae

Choristoneura murinana (Hübner) - Silver fir shoot tortricid 12
Tortrix viridana Linnaeus - European oak leafroller 14

Family: Lasiocampidae

Dendrolimus sibiricus Tschetverikov - Siberian coniferous silk moth 16
Malacosoma neustria (Linnaeus) - European tent caterpillar 18

LARGER WOODBORERS 21

Family: Buprestidae

Agrilus biguttatus (Fabricius) - Two spotted oak borer 22
Agrilus planipennis Fairmaire - Emerald ash borer 24

Family: Cerambycidae

Anoplophora glabripennis (Motschulsky) - Asian long-horned beetle 26
Callidiellum rufipenne (Motschulsky) - Smaller Japanese cedar longhorned beetle 28
Cerambyx cerdo Linnaeus - Great Capricorn beetle 30
Monochamus sartor (Fabricius) 32
Monochamus urussovi (Fischer) - Black fir sawyer beetle 34
Oberea linearis (Linnaeus) - Hazelnut longhorned beetle 36
Oberea oculata (Linnaeus) - Eyed longhorn beetle 38
Plagionotus arcuatus (Linnaeus) 40
Saperda carcharias (Linnaeus) - Large poplar longhorned beetle 42
Saperda perforata (Pallas) 44
Tetropium castaneum (Linnaeus) - European spruce longhorn beetle 46
Tetropium fuscum (Fabricius) - Brown spruce longhorn beetle 48
Tetropium gracilicorne Reitter - Thin-antenna spruce borer 50

Xylotrechus altaicus Gebler - Altaï larch longhorn beetle 52
Xylotrechus rufilius Bates 54
Family: Curculionidae
Pissodes harcyniae (Herbst) - Spruce weevil..... 56
Family: Siricidae
Sirex noctilio Fabricius - Sirex woodwasp 58
Sirex rufiabdominis Xiao & Wu - Red-bodied horntail..... 60

BARK BEETLES 63
Family: Scolytidae
Dendroctonus armandi Tsai & Li - Large pitch tube bark beetle 64
Dendroctonus micans (Kugelann) - Great spruce bark beetle 66
Hylastes ater (Paykull) - Black pine bark beetle..... 68
Hylesinus varius (Fabricius) - Ash bark beetle 70
Hylurgus ligniperda Fabricius - Red-haired pine bark beetle 72
Ips hauseri Reitter - Hauser's engraver..... 74
Ips sexdentatus (Boerner) - Six-spined engraver beetle 76
Ips subelongatus (Motschulsky) - Larch bark beetle..... 78
Ips typographus (Linnaeus) - European spruce bark beetle 80
Pityogenes chalcographus (Linneaus) - Six-spined spruce bark beetle..... 82
Scolytus intricatus (Ratzeburg) - European oak bark beetle 84
Scolytus morawitzi (Semenov) - Morawitz's bark beetle..... 86
Scolytus ratzeburgi Janson - Birch bark beetle 88
Tomicus piniperda (Linnaeus) - Common pine shoot beetle 90

Introduction

Trees and forested areas are invaluable resources as they provide ecological, economic, spiritual and social benefits to all within Canada.

Human activities impact the surrounding environment by altering the structure and dynamics of ecosystems. The rate and extent of global trade and human migration have increased dramatically over the years. This expansion has increased the probability that organisms can be accidentally moved to and become established in areas outside of their natural range.

Most organisms fail to survive when introduced into a new environment or moved over long distances. Sometimes the conditions are suitable for an introduced organism to survive, find an appropriate food source and successfully reproduce in its new environment. Once established, their population levels may increase rapidly because the predators, parasites and diseases which attack them in their native range are not usually present in the new environment. Canadian forests have been dynamically evolving since the last ice age (~10, 000 years ago) in response to fire, climate and indigenous insects and diseases. When exotic forest pests become established, trees are abruptly exposed to a new invasive species and may not have the mechanisms to defend themselves.

In conjunction with the absence of population-limiting factors, the establishment of introduced forest pests may lead to either localized or large scale tree mortality that can impact private residences, municipalities, industries and forest ecosystems. Recently, the Emerald Ash Borer (*Agrilus planipennis*), a metallic woodborer native to China, has become established in North America where it is causing extensive mortality to green and white ash trees and threatens to severely limit the distribution of these species. However, in this insect's native range such damage has rarely been observed.

The Canadian Food Inspection Agency (CFIA) has a mandate, under the federal Plant Protection Act, to protect Canada's plant resource base against the introduction and spread of quarantine pests according to standards outlined in the International Plant Protection Convention. The CFIA does this by developing import, export and domestic regulatory policies and associated inspection, surveillance and eradication programs.

PATHWAYS OF INTRODUCTION

In terms of introduced organisms, pathways can be defined as means by which organisms are moved to new environments. Various plant health policies have identified that the greatest risks of introducing forest insects are generally associated with the importation and domestic movement of:

- Wood packaging material
- Shipping containers
- Nursery stock
- Firewood
- Raw logs with bark
- Christmas trees
- Personal effects

Wood packaging material can be one of the most important pathways for the introduction of exotic forest insects because it is often used to ship a wide variety of consignments (e.g. steel products, granite, break bulk, glass, machinery, vehicles, consumer products, etc.).

The risk posed by wood packaging varies with wood quality and degree of finishing. The higher the grade and degree of finishing, the less likely the possibility of infestation.

In the past, many exotic plant pests have been intercepted on loose wood dunnage, pallets, crating or other wood packaging made from low grade material from various origins. North America has recently agreed to begin the implementation of a new International Plant Protection Convention standard (ISPM #15) that will regulate the movement of international wood packaging.

Cities and urbanized areas have higher probabilities of receiving exotic forest pests because of the large volume of goods that are imported into those areas. Urban trees and forested areas are often exposed to poor growing conditions due to soil compaction, air pollution, mechanical damage, etc. The combination of these factors increases their vulnerability to exotic forest pests.

CFIA forest pest surveillance programs target the routes of these pathways and high risk locations (e.g. international ports or terminals, industrial zones, landfills and storage sites, nurseries, etc.). For example, high risk consignments within transport containers are inspected at major ports before they are permitted to enter Canada. However, only a small proportion of these containers are inspected upon entry and therefore, a large volume of uninspected wood packaging material is transported to urban and rural centres throughout Canada. As it is a tremendous undertaking to monitor the introduction of forest pests in a country the size of Canada, it is important to have many additional "eyes" that are on the lookout for exotic organisms.

OBJECTIVES

This book is designed for public and private sector Canadians who work in the areas of tree health and arboriculture. This book focuses more on insect descriptions, host tree preferences, damage symptoms and geographic distribution rather than insect biology in order to increase the probability of finding exotic pests during tree health assessments. A key issue in the eradication of quarantine insects is discovering and identifying populations while they are still at low and controllable levels. Hopefully this book will serve as an early detection tool.

This book is intended to help detect exotic forest insects and should be used in conjunction with indigenous pest field guides. However, the information within this book will **not** transform the reader into an expert in insect identification. Some exotic insects, especially bark beetles, may resemble indigenous or naturalized insects. Some of the damage caused by exotic and indigenous forest insects may also be very similar (e.g. red needles). Therefore, suspect specimens need to be examined by professional entomologists for conclusive identification.

Most of the insects included in this book could pose a serious threat if they became established in Canada. However, there are a few that have already become established and are being eradicated and/or regulated. The insects within this book do not represent a complete list of exotic forest insects which could invade Canada. There are a large number of non-indigenous insects throughout temperate forest regions in the world and only a very small portion of these has been included.

How to Use this Book

BOOK FORMAT

Descriptions of insects in this book are organized by guilds, which represents similarities in their biology and the part of a tree in which they breed. Bark beetles are small insects that usually feed beneath the bark on phloem. Woodborers are a diverse assemblage of round and flat-headed wood borers, wood wasps, weevils and other insects that feed within the wood. Defoliators are primarily moths, the larvae of which feed on foliage or needles. Within this guidebook, these guilds are colour coded for convenient referencing. The insects are also arranged alphabetically within each guild and each family.

For many exotic insects scientific information may be difficult to obtain. Some insects have not been extensively studied in their native range. Therefore, there is some variation in the amount of information presented for each insect.

For each insect, information is arranged into 6 categories:

- Identification
- Host trees
- Location of infestation within the tree
- Host condition
- Distribution
- Signs and symptoms

Identification briefly describes some of the key anatomical features that distinguish one insect from another.
Host trees indicates which trees, by genus, are known hosts of an insect.
Location of infestation within the tree describes the parts (roots, root collar, bole, branches, etc.) and tissues (foliage, phloem, sapwood, heartwood, etc.) that are attacked by the various life stages of the insect.
Host condition outlines the health status, age and size of trees that are attacked.
Distribution lists the countries or regions in which the insect is either native or has been introduced.

Signs and symptoms describes the characteristics that are indicative of insect attack (signs such as colour of frass, exit hole size and shape, egg gallery shape, etc.) and outlines a tree's response to attack by the insect (symptoms such as resinosis, fading foliage, thinning crown, etc.). Literature cited within the text of this book is assigned a unique number. Citations can be looked up in the Reference section at the back of the book.

Two cross-reference indexes are provided. The first index can help determine which insects will attack specific parts of a given tree. The second index indicates which tree genera are known hosts of specific insects.

Wherever possible, non-scientific language is used throughout this book to describe the insects. However, in some instances entomological terminology is used. A glossary is located at the end of the guidebook to define these terms.

DETECTING EXOTIC FOREST INSECTS

Detecting newly introduced forest insects can be very difficult because the population may be localized and still at very low densities. Furthermore, the signs and symptoms may be masked by other factors. However, there are specific clues that can be used to increase the likelihood of detection. General symptoms of decline in coniferous trees are a thin crown, stunted leader (i.e. top) and a chlorotic or reddening crown. In broad-leaved trees, epicormic shoots, wilted leaves, thin crown and pre-mature foliage colour change are common indications of decline. Although these symptoms characterize many other types of forest health stress factors (e.g. drought, root disease, hail damage, insects, mammals, salt damage, sun scald), they are also the most obvious external indicators of exotic insects.

Obtaining a "search image" for these symptoms is an initial step in locating potentially infested trees. As many exotic forest insects tend to breed in stressed trees, it is important that inspectors and surveyors check all obviously declining trees. This is particularly important in urban areas where trees often grow in sub-optimal conditions and are subjected to many stress factors.

In order to find infested trees, the surveyor must scan the entire length of a tree. Vigilance and general observation for declining trees is most beneficial. Scanning trees while walking through parks, sparsely treed industrial areas, woodlots, fencerows, riparian corridors or other wooded areas is critical in quickly locating and identifying an early attack.

General symptoms of decline should draw attention to a tree or a group of trees. The next step is to determine the causal agent. Familiarity with indigenous or naturalized biotic and abiotic forest health factors as well as local site conditions will greatly enhance the likelihood of an accurate assessment. External signs of insect activity include the presence of larvae or adults, frass (within bark cracks or crevices, on understory leaves, at the base of the tree, etc.), exit holes, entrance holes, pitch tubes along the bole, resinosis, gouting, oviposition niches, defoliation (partial or complete) and silk webbing. Internal signs such as egg and larval galleries, tunnels within twigs or branches, pupal chambers and the presence of various insect life stages can be uncovered by removing portions of the outer and inner bark with an axe or knife. Permission from the landowner is always required for more invasive investigations.

If the cause of tree decline seems suspicious, contact your local municipal or city forester, provincial ministry of natural resources entomologist/pathologist or professional arborist. Record pertinent information (street address or geographical coordinates, tree species affected, observable signs and symptoms, etc.) and if possible, collect a specimen (preferably adults) as these will assist professionals in evaluating the situation.

SAMPLE SPECIMEN SUBMISSION

This guidebook should assist in recognizing the presence of introduced forest insects but it can not replace the years of specialized training required to correctly identify insect species. There are many anatomical characteristics that require microscopic examination by specialists. The "Identification" section within the text of this guidebook only provides a general description of an insect and does not contain enough information to allow the reader to dependably identify an insect to the species level. If all other sources (e.g. local forest health specialists, native forest insect guidebooks, etc.) are unable to provide a definitive identification of a forest pest, please contact a Plant Health specialist at your local Canadian Food Inspection Agency office (http://www.inspection.gc.ca).

Survey Biologist
Canadian Food Inspection Agency

DEFOLIATORS

- Lymantriidae
- Tortricidae
- Lasiocampidae

Lepidoptera: Lymantriidae

Calliteara pudibunda (Linnaeus)

Pale tussock moth

IDENTIFICATION

Adult: Adults are robust light gray to gray-brown moths with a wingspan of 40 to 62 mm in females and 33 to 45 mm in males.[2, 47] The front wings are light gray to gray-brown with rust-coloured spots and two dark transverse bands. The hindwings are dirty white to almost white.[2, 47] While at rest, adult moths extend their large, white and densely hairy front legs.[2, 47] Males have densely pectinate antennae.[2, 47]

Larva: Larvae are usually bright yellow-green but can appear brownish. Larvae have four erect, yellow-white, dorsal tufts on segments 4 through 7 with black transverse colouration between each tuft. Third instar larvae also have a distinguishable erect, red, hair-pencil on the 11th segment.[2, 47]

Egg: Eggs are gray-blue, oblate spheroid (pumpkin shaped) with a slight, dark depression on the top.[2, 47]

HOST TREES

Acer, Aesculus, Betula, Carpinus, Castanea, Corylus, Fagus, Juglans, Quercus, Populus, Salix, Sorbus, Tilia and *Ulmus*.[2, 47] Prefers *Fagus* and *Carpinus*[2, 47]

LOCATION OF INFESTATION WITHIN THE TREE

Larvae feed on foliage within the crown.[2, 47]

HOST CONDITION

Healthy trees.[2, 47]

DISTRIBUTION

Europe, central Asia, China and Japan.[2, 47]

SIGNS AND SYMPTOMS

Eggs are usually deposited on the bark of tree trunks and on foliage, in flat masses of 50 to 300 eggs.[2, 47]

Young larvae gather on the underside of leaves. Their feeding activity punctures the leaf tissue creating holes which may contain a few uneaten veins or the holes may be completely clear.[2] Mature larvae devour the entire leaf.[2, 47] Pieces of uneaten leaves, frass and branchlets can be found on the forest floor because mature larvae are wasteful eaters.[2, 47] Severe defoliation causes thinning in the canopy (i.e. increased sunlight penetration to the forest floor).[47] Branch tip die-back, up to 30 cm, can also occur during heavy infestations.[47] Outbreaks can result in complete defoliation of the host tree by the end of summer and cause mortality in young trees.[2, 47]

A

Adult *C. pudibunda*. Note two dark transverse bands on front wings.

B

Adult *C. pudibunda* extending white, hairy front legs.

C

Pumpkin-shaped *C. pudibunda* eggs. Note black depression on the top.

D

Bright yellow-green *C. pudibunda* larva. Note red hair-pencil.

E

C. pudibunda larva. Note four erect, yellow-white, dorsal tufts.

Lepidoptera: Lymantriidae

Lymantria dispar (Linnaeus)

Gypsy moth

IDENTIFICATION

Adult: Male moths are much smaller than females and have a wing span of 35 to 40 mm.[1] Females have a wingspan of 55 to 70 mm. Males are brown whereas females are mainly white. Both sexes have a dark, crescent-shaped mark on the forewing.[1, 2, 39] Both sexes also have pectinate antennae, however the males have longer branches that give their antennae a more feathery appearance.[1]

Larva: The 1st (3 mm) and 3rd (7 mm) instars are black with long hairs; the 2nd instar (5 mm) is brown with short hairs. Instars 4, 5 and 6 are similar to each other and may be light to dark gray with flecks of yellow. They have long hairs that may be dark or golden and have 2 rows of tubercles along the back. Normally 5 pairs of blue tubercles are followed by 6 pairs of red, however variations are known to occur including all 11 pairs of tubercles being blue.[1]

Egg: Ovoid egg masses are covered with tan coloured hairs from the female's abdomen. They eventually become sun bleached with age. Egg masses are approximately 30 to 60 mm long and 20 to 30 mm wide and may contain 100 to 1000 eggs.[1, 4] Spent egg masses have pin-sized holes caused by emerging larvae.[39]

HOST TREES

Quercus (main host), *Acer, Alnus, Betula, Crataegus, Fagus, Malus, Populus, Prunus, Salix, Tilia* and many other tree and shrub species.[1, 36, 39]

LOCATION OF INFESTATION WITHIN THE TREE

Larvae feed on foliage within the crown.[2]

HOST CONDITION

Healthy trees.[4]

DISTRIBUTION

Europe, northern Africa, Asia, eastern Canada and northeastern USA.[1]

SIGNS AND SYMPTOMS

Typically near their pupation sites, female moths lay egg masses on tree bark, branches and other protected places including rock piles, lawn furniture, bird houses, piles of wood, beneath logs, underneath recreational vehicles or equipment, etc.[4]

Early instar larvae excavate small holes in leaves and feed gregariously.[2] As the larvae grow they make larger holes and they also consume the leaf margin.[1] Final instar larvae will consume the entire leaf. At high populations, larvae can strip all leaves from a tree.[1] At low populations, feeding may be barely noticeable and larvae may be difficult to find since they prefer to rest in dark locations under bark flaps, stones, litter on the ground, etc.[4] Larvae seek sheltered places to pupate.[57] Pupae may be found attached by silken thread to branches, tree trunks, rocks, forest debris, buildings or fences.[57]

During outbreaks large amounts of frass may fall from defoliated trees.[4] When food is scarce, larvae will also feed on unripe tissues of annual shoots, flowers and buds.[2] One year of defoliation may not kill a healthy tree. Severe defoliation can reduce tree growth and predispose trees to attack from other insects and diseases. Four successive years of defoliation can cause mortality, especially in weakened or stressed trees.[58]

A

Larger and mainly white female (top). Smaller and mainly brown male (bottom). Note dark crescent-shaped mark on forewings.

B

Female *L. dispar* moth ovipositing an ovoid egg mass. Egg masses are covered with tan coloured hairs from the female's abdomen.

C

L. dispar larva. Note five pairs of blue tubercles are followed by six pairs of red.

D

Defoliation by early instar *L. dispar* larvae. Note small holes in the leaves.

E

Defoliation by late instar *L. dispar* larvae. Note consumed leaf margin.

F

Extensive stand defoliation caused by *L. dispar*.

Lepidoptera: Lymantriidae

Lymantria monacha (Linnaeus)

Nun moth

IDENTIFICATION

Adult: Nun moths are moderately sized, hairy and often stout-bodied with a wingspan of 45 to 55 mm (female) or 35 to 45 mm (male).[2, 4] Moths have white forewings with numerous dark, transverse, wavy lines (arches) and patches. The hind wings are gray-white or gray-brown, with minute dark patches along the outer edge.[2, 4] Female antennae are short and saw-like, whereas male antennae are feathery.[2, 4] Females have a reddish-brown abdomen with black spots, males have a gray-black abdomen.[2, 4] Melanic gray-brown and black forms are also known to occur.

Larva: Mature larvae are light to dark brown and have an orange to pale-brown head with dense black markings. Larvae are 30 to 35 mm long. Numerous short black and white hairs are present; hairs on the prothoracic and anal segments are longer. The 1st four abdominal segments have a dorsal pair of small, bluish glandular protrusions; the 6th and 7th segments have prominent mid-dorsal, orange glandular warts.[2, 4] A dark dorsal band runs from the 2nd to the 11th segment.[2, 4]

Egg: Eggs are initially orange-brown or purplish, turning dark brown over time, 1 mm in diameter, spherical and slightly concave in the centre.[4, 43, 94]

HOST TREES

Prefers *Picea, Larix, Abies, Pinus* and *Pseudotsuga*.[1, 4, 94] Will also feed on *Acer, Betula, Carpinus, Fagus, Fraxinus, Malus, Prunus, Quercus, Ulmus* and other fruit trees.[1, 4, 94]

LOCATION OF INFESTATION WITHIN THE TREE

Larvae feed on needles or leaves. First instars prefer newly expanded foliage or young male flowers, whereas older larvae can feed on new and old foliage.[4, 94, 95, 96]

HOST CONDITION

Healthy trees.[4]

DISTRIBUTION

China, Japan, Korea, Russia, Turkey and Europe.[1, 4]

SIGNS AND SYMPTOMS

Naked clusters of eggs may be found in bark crevices or under bark scales of trees and logs, wood packaging, forest products, sea containers and ships.[1] Egg clusters are not covered with the abdominal hair of females.[4] On coniferous trees, female nun moths preferentially oviposit on the lower bole, but during outbreaks oviposition will occur on the upper bole and in the crown.[95]

Gymnosperms

First instar larvae will only feed on the foliage of newly expanded shoots and are unable to consume older needles.[4] Second and third instar larvae are able to feed on older foliage but prefer to feed on new needles.[4, 95] Larvae can be wasteful feeders and may only consume the base of a needle, resulting in partially uneaten needles falling to the ground.[94] The crowns of defoliated trees appear thinned and have a reddish-brown colour. During outbreaks, over 50% of the foliage can be defoliated. Severe defoliation over a few years can cause tree mortality.[95]

Angiosperms

Initially, larval browsing creates holes in the leaves.[7] As feeding progresses, leaves are entirely consumed except for the middle vein.[96]

A

Adult *L. monacha*. Note white forewings and numerous dark, transverse, wavy lines and patches.

B

Thin crowns caused by *L. monacha* defoliation.

C

Mature dark brown *L. monacha* larva (30-35 mm long). Note mid-dorsal orange warts on the 6th and 7th segments.

D

Bark scale removed to reveal naked *L. monacha* egg mass.

E

L. monacha defoliation on understory host tree.

F

Extensive stand defoliation caused by *L. monacha*. Note thinning reddish-brown crowns.

G

Defoliation by late instar *L. monacha*. Note partially eaten needles.

Lepidoptera: Tortricidae

Choristoneura murinana (Hübner)

Silver fir shoot tortricid

IDENTIFICATION

Adult: Moths have a wingspan of 17 to 25 mm.[2] Forewings are gray and yellow with variable brown markings and a characteristic broad, red-brown transverse band.[2] Hind wings are gray-brown with yellowish tips.[2]

Larva: Newly hatched larvae are green-yellow with a brown head, and are 1.5 mm long.[2] Second instar larvae are dark yellow with a yellow-brown head.[2] Mature larvae, 16 to 22 mm long, have a shiny black head and a pale gray-green body with lighter lateral and ventral segments.[2] They also have an orange anal shield.[2] Chitinized warts with black hairs occur over the entire body.[2, 13]

Egg: Eggs are 1.5 by 1.2 mm, somewhat flat, slightly green, oval and characteristically rimmed.[2]

HOST TREES

Abies (main host), *Cedrus, Juniperus, Picea, Pinus* and *Pseudotsuga*.[13]

LOCATION OF INFESTATION WITHIN THE TREE

Larvae feed on foliage in the crown.[2]

HOST CONDITION

Healthy trees.[2] Prefer forests with a large percentage of *Abies*. Mature trees are preferred but larvae will also feed on young trees.[126]

DISTRIBUTION

Central and southeastern Europe.[2, 13]

SIGNS AND SYMPTOMS

Eggs are predominantly deposited in the upper crown of host trees, in two overlapping rows on the upper side of the needle.[2, 13, 126] Females oviposit approximately 10 to 30 eggs within these two rows and up to 100 eggs in total.[2]

Immediately after hatching, 1st instar larvae seek hibernation sites between the bud scales or bark cracks and spin fine white hibernacula within which they moult and pass the rest of the summer and the following winter.[126] First instar larvae do not feed.[13] In the spring, 2nd instar larvae penetrate new unopened buds, weave silk threads over the bud scales and cause the developing shoot to become characteristically bent.[2, 126] Unlike North American coniferophagous *Choristoneura* species, *C. murinana* larvae only feed on newly formed needles and will not feed on older needles, even during outbreaks.[2, 13, 126]

Early instar larvae create holes in the needles and often leave behind partially eaten stubs, while older instars consume the entire needle.[2] On rare occasions, the epidermis and inner bark of young shoots are consumed. Defoliation primarily occurs in the upper crown, but will also occur in the lower crown during outbreaks.[2] Pupation normally occurs in the foliage.[13]

Symptoms of attack include loss of newly flushed needles, decrease in annual height increment and gradual thinning and rounding of the crown.[2] Defoliated crowns may appear reddish-brown. Mortality occurs on trees experiencing two or more consecutive years of severe defoliation.[126] Cones do not develop because feeding occurs on flower buds.[2]

A

Adult *C. murinana*. Forewings are gray and yellow with brown markings.

B

C. murinana larva. Note silk threads and partially consumed needles.

C

C. murinana larva. Note black head.

D

Mature *C. murinana* larva.

E

C. murinana only feeds on new foliage. Note reddish-brown colour of damaged shoots.

F

C. murinana defoliation from the previous year.

Lepidoptera: Tortricidae

Tortrix viridana Linnaeus

European oak leafroller

IDENTIFICATION

Adult: Forewings are pale-green or yellow-green; hindwings are brownish-gray to grayish; both wings have a white, frayed outer edge.[6, 36, 42, 87] The wingspan is approximately 18 to 23 mm.[6, 42, 87] The head is yellowish and adults have a grayish, 8 mm long abdomen.[6, 42]

Larva: Younger larvae are gray coloured with dark heads.[6] Older instar larvae turn gray-green.[6] Larvae are 15 to 19 mm long and 2.5 mm wide.[42]

Egg: Eggs are round, with a diameter of about 0.7 mm.[6, 42] They are initially light yellow, later changing to brown.[6, 42]

HOST TREES

Quercus (main host), *Acer, Betula, Carpinus, Fagus* and *Populus*.[6, 42] They also feed on shrubs including *Vaccinium* and *Urtica*.

LOCATION OF INFESTATION WITHIN THE TREE

Larvae feed on foliage, with the most preferable section being the upper crown.[6]

HOST CONDITION

Drought stressed and healthy hosts. Pole-sized and older trees are preferred.[6]

DISTRIBUTION

Europe, northern Africa, Cyprus, Iran and Israel.[6, 36, 42, 83]

SIGNS AND SYMPTOMS

Each female oviposits approximately 50 to 60 eggs in pairs within a cement-like mass.[42, 76, 87] Eggs are deposited on branches, leaves, and branch forks, within the entire crown.[6] A dust and algae lining make the eggs nearly invisible.[6]

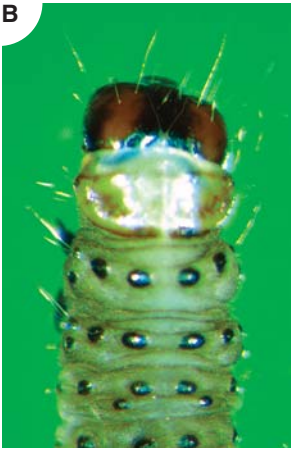
Emerging larvae bore into open buds, since closed buds cannot be penetrated.[6] Therefore, emerging larvae can only survive if the buds are in synchrony with their development.[6] As the buds flush, the larvae move to young leaves and flowers and continue feeding.[6, 42] Larvae construct shelters by rolling leaves with silk webbing.[42] Third instar larvae become more mobile and are thus more visible. Similar to other tortricids, when larvae are disturbed, they will drop on a silken thread.[34] Last instar larvae feed upon the expanded foliage as well as the bark of tender young shoots.[42, 76]

Tortrix viridana is part of a *Quercus* die-back complex that results in thinning foliage, progressive die-back, cambial necrosis, epicormic shoot development and tree mortality.[80, 81, 83] Successive defoliation can cause growth loss and can also weaken trees and predispose them to mortality by other organisms.[42]

A

Adult *T. viridana* (18-23 mm wingspan). Note pale-green forewings and frayed outer edge.

B



Gray-green *T. viridana* larva (late instar).

C

T. viridana larva (15-19 mm long).

D

Rolled leaf shelters created by *T. viridana* larvae.

E

Thinned crowns caused by *T. viridana* defoliation.

F

Rolled leaf shelters created by *T. viridana* larvae.

Lepidoptera: Lasiocampidae

Dendrolimus sibiricus Tschetverikov

Siberian coniferous silk moth

IDENTIFICATION

Adult: Moths are yellowish-brown or light gray to dark brown or almost black.[4] The front wings have two dark transverse bands and a white spot in the centre. The hind wings are the same base colour as the forewings but without any markings.[1] Males are approximately 30 mm long and have a wing span of 40 to 60 mm. Females are approximately 40 mm long and have a wing span of 60 to 80 mm.[4, 24]

Larva: Larvae are mainly black or dark brown with numerous spots and long hairs.[4, 24] Reddish setae are found on the sides of larvae, usually as red jagged bands or spots.[1] The 2nd and 3rd segments are marked with blue-black stripes. Larvae are approximately 55 to 70 mm long.[4, 24]

Egg: Eggs are 2.2 mm long and 1.9 mm wide (oval). They are initially light-green but turn creamy-white and finally darken and become spotted.[24]

HOST TREES

Abies, Larix, Picea, Pinus and *Tsuga.*[4, 24]

LOCATION OF INFESTATION WITHIN THE TREE

Larvae feed on foliage in the crown.[4, 24]

HOST CONDITION

Stressed (e.g. drought) and healthy trees.[4, 24]

DISTRIBUTION

China, Mongolia, Japan, Korea, Kazakhstan and Russia.[4]

SIGNS AND SYMPTOMS

Female moths oviposit a single egg or clusters (an average of 200 to 300 eggs) of egg chains primarily on needles in the lower part of the crown. However, during outbreaks eggs are laid throughout the tree and even on the ground.[4, 24]

First instar larvae preferentially consume the edges of needles.[4, 24] Older larvae will completely consume entire needles and may sometimes eat the bark of young shoots and cones.[24] Defoliated crowns appear reddish-brown.[16]

Severe defoliation over a few years can lead to direct tree mortality or it can predispose host trees to attack by secondary insects.[4, 24] In it's native range, *D. sibiricus* outbreaks can cause severe tree mortality over very large areas.[4, 24]

Mating *D. sibiricus* moths. Note two dark transverse bands and white spot on forewing.

D. sibiricus larva (55-70 mm long).

Reddish-brown crowns of trees defoliated by *D. sibiricus*.

Oval *D. sibiricus* eggs (1.9 mm wide).

D. sibiricus larva. Note red bands on the side of the larva.

D. sibiricus larva. Note 2nd and 3rd segments with blue-black stripes.

D. sibiricus cocoon.

Lepidoptera: Lasiocampidae

Malacosoma neustria (Linnaeus)

European tent caterpillar

IDENTIFICATION

Adult: Adult moths vary greatly in colour.[2, 111] There are two common morphs, one light and one dark, with less frequent intermediates. The basic colour is brown, but can range from ochre-yellow to red-brown.[2, 111] Males have a wingspan of 30 to 40 mm, with the more robust females having a wingspan of 36 to 40 mm.[2, 111] Forewings have a brownish, narrow-edged, oblique, central transverse band.[2, 111] The fringes of the forewings are irregularly variegated and checkered.[2, 111] Male and female antennae are bipectinate, with females having shorter antennal branches and shorter antennae.

Larva: First instar larvae are black and approximately 2 mm long.[111] Mature larvae are 40 to 55 mm long, slender and are covered with numerous fine secondary setae.[2, 111] Larvae are marked with a distinct white dorsal line and blue or gray-blue, and red-yellow lateral bands separated by black edging.[2, 111]

Egg: Eggs are white or gray-brown.[111]

HOST TREES

Acer, Alnus, Amygdalus, Betula, Carpinus, Castanea, Cotoneaster, Corylus, Crataegus, Fagus, Juniperus, Larix, Malus, Morus, Populus, Prunus, Pyrus, Quercus, Rosa, Rubus, Salix, Sorbus, Syringa, Ulmus and occasionally *Tilia* and *Fraxinus*.[111]

LOCATION OF INFESTATION WITHIN THE TREE

Larvae feed on foliage within the crown.[111]

HOST CONDITION

Healthy trees.[111]

DISTRIBUTION

China, Europe, Iran, Japan, Korea, Mongolia, northern Africa, Siberia, Syria, Taiwan and Turkey.[111]

SIGNS AND SYMPTOMS

Eggs are deposited in masses of 150 to 400 and are cemented together by a frothy varnish-like material. Similar to other *Malacosoma* species, eggs are deposited in a band (1 cm wide) around 1 and 2 year old branch tips.[70, 111]

Newly emerged larvae immediately crawl to the crown. Larvae feed gregariously and gather at major branch forks to construct tents.[111] Although larvae feed within these tents, they also feed throughout the entire crown.[111] Larvae can completely defoliate trees during outbreaks.[111]

As larvae develop they become solitary and eventually seek sheltered locations to pupate such as bark crevices, between dried leaves on the tree stem or branches, in leaves on the ground or in the cracks of buildings.[111] Cocoons are yellowish-white and may occur in clusters.[70, 111]

Defoliation can cause growth loss and can predispose host trees to mortality by other organisms.[111] Trees may be killed after a few years of severe defoliation.[111]

A

Adult *M. neustria* (dark morph). Note central transverse band.

B

Complete defoliation of host tree during a *M. neustria* outbreak. Note silk tents.

C

M. neustria larvae. Note white, gray-blue and red-yellow bands separated by black edging.

D

M. neustria larvae on silk tent.

E

M. neustria egg mass (1 cm wide).

F

Foliage partially consumed by *M. neustria* larva.

G

Male *M. neustria* (light morph).

LARGER WOODBORERS

- Buprestidae
- Cerambycidae
- Curculionidae
- Siricidae

Coleoptera: Buprestidae

Agrilus biguttatus (Fabricius)

Two spotted oak borer

IDENTIFICATION

Adults are cylindrical, metallic beetles, 8 to 13 mm long, ranging in colour from golden-green, green, blue-green, blue to violet.[42, 129] The elytra are slender and have two white spots near the posterior end of the elytral suture.[42, 129] The frons is wide and flat, with a shallow depression.[129] The length of the pronotum is one and a half times the width.[129]

HOST TREES

Quercus (main host), *Fagus* and *Castanea*.[98, 130] *Quercus rubra* is a known host tree occurring within Canada.[98]

LOCATION OF INFESTATION WITHIN THE TREE

Larvae feed on the inner bark and sapwood along the entire bole (including stumps) and larger diameter branches.[120, 129, 130] Immature beetles maturation feed on host tree leaves.[42, 98, 120]

HOST CONDITION

Standing trees (especially if weakened by defoliation, frost damage or water stress) or recently downed trees and stumps.[98, 120, 129, 130] In it's native range, larvae will not develop in dried dead trees.[120] Healthy trees are also susceptible to attack.[98, 120] Although beetles prefer larger diameter (i.e. greater than 30 cm) and older (i.e. 50 to 120 years) trees, attacks have also been recorded on 20 year old hosts.[98, 120]

DISTRIBUTION

Europe, Middle East, Siberia and northern Africa.[42, 98, 120]

SIGNS AND SYMPTOMS

Females oviposit clusters of 5 to 6 eggs on the bark of host trees.[42, 120, 129] Larvae bore through the bark and excavate frass-filled, zig-zagging galleries which can reach lengths of 155 cm.[42, 98, 120] Early instar larvae generally make their galleries along the wood grain while older instars produce galleries in irregular twisting transverse directions.[42, 98, 120] These galleries are not as distinctly "S-shaped" as those created by the emerald ash borer, *Agrilus planipennis*. Dark cracks and discolouration of the bark and cambial tissue may occur over the galleries as the tree tries to defend itself from the invasion.[98, 120]

Larvae overwinter in 10 to 14.8 mm by 3 to 4.5 mm chambers within the inner bark.[42, 120] Woodpecker activity on living trees may indicate overwintering larvae.[120] Beetles emerge from "D-shaped" exit holes that are about 2.5 by 3.0 mm and are found from ground level up to a height of 10 m (i.e. lower portion of the crown).[42, 98, 120]

Larval galleries can girdle the host tree resulting in twig and branch die-back, changes in foliage colour from green to brown, thinning of foliage within the crown, development of epicormic shoots along the stem and tree mortality in heavily infested trees.[42, 98, 120]

Adult *A. biguttatus* (8-13 mm long). Note white spots near elytral suture.

Zig-zag shaped larval galleries (up to 155 cm long).

Branch and twig dieback caused by *A. biguttatus*.

A. biguttatus larva just prior to pupation.

Mature *A. biguttatus* larva.

D-shaped exit hole (2.5 by 3.0 mm) of *A. biguttatus*.

Early instar larval galleries. Note zig-zag shape.

Coleoptera: Buprestidae

Agrilus planipennis Fairmaire

Emerald ash borer

IDENTIFICATION

Adult beetles are metallic blue-green, narrow, hairless, elongate, 8.5 to 14.0 mm long and 3.1 to 3.4 mm wide.[86] The head is flat and the vertex is shield-shaped.[86] The eyes are bronze or black and kidney shaped.[86] The prothorax is slightly wider than the head and is transversely rectangular, but is the same width as the anterior margin of the elytra. The posterior margins of the elytra are round and obtuse with small tooth-like projections on the edge.[86]

Mature larvae are 26 to 32 mm long and creamy white.[86] The body is flat and broad shaped.[86] The posterior ends of some segments are bell-shaped. The abdomen is 10-segmented. The 1st 8 segments each have one pair of spiracles and the last segment has one pair of brownish, pincer-like appendages.[86]

HOST TREES

Fraxinus, Juglans, Pterocarya and *Ulmus*.[86] In North America, only *Fraxinus* has been found infested to date.

LOCATION OF INFESTATION WITHIN THE TREE

Larvae feed on the inner bark and sapwood along the entire bole and larger branches (greater than 2.5 cm diameter) in the crown. In addition to mature trees, galleries can occur in young saplings. Immature beetles maturation feed on leaves.[86]

HOST CONDITION

Healthy or weakened trees.[86]

DISTRIBUTION

China, Japan, Korea, Mongolia, Russia and Taiwan. Introduced to Canada (Essex, Lambton & Elign Counties and Chatham-Kent Municipality, Ontario) and USA (Michigan, Illinois, Indiana and Ohio).[1, 86]

SIGNS AND SYMPTOMS

Immature beetles maturation feed on host tree foliage, creating irregular notches in the leaves.[86] Eggs are laid singly on the bole or branches.[86] First instar larvae bore through the bark and feed on the inner bark and the outer sapwood, eventually forming flat and wide (6 mm), "S-shaped" galleries that are filled with a fine brownish frass.[86] Galleries are 9 to 16 cm long (up to 20 to 30 cm) and increase in width from the beginning to the end.[86] Galleries can occur along the entire bole and in branches that are at least 2.5 cm in diameter.[86] Callus tissue may be produced by the tree in response to larval feeding and may cause vertical bark cracks to occur over a gallery.[86]

Pupation takes place at the end of a gallery just beneath the bark, or near the surface of the sapwood (5 to 10 mm) and even in the corky tissue of thick-barked trees.[86] Beetles emerge through "D-shaped" exit holes, 3.5 by 4.1 mm in size.[86] These holes are very difficult to find so careful inspection is required.[86] Woodpecker activity may also indicate the presence of this beetle.[86] Dying or dead trees, particularly with bark sloughing off and crown die-back can also be used as indicators of attack.[86] Other signs of attack include a thinning crown, epicormic shoots, and vertical cracks on the trunk.[86]

A

Adult *A. planipennis* (8.5-14 mm long). Metallic, green-blue body.

B

Various larval instars of *A. planipennis*.

C

S-shaped larval galleries of *A. planipennis*.

D

D-shaped exit hole (3.5 by 4.1 mm) of *A. planipennis*.

E

Epicormic shoots caused by *A. planipennis*.

F

Vertical bark cracks over larval galleries caused by callus tissue production.

G

Thinned ash crowns infested with *A. planipennis*.

Coleoptera: Cerambycidae

Anoplophora glabripennis (Motschulsky)

Asian long-horned beetle

IDENTIFICATION

Adults are large shiny black beetles, 20 to 35 mm long and 7 to 12 mm wide. There are up to 20 irregular white spots on each elytron. There is one prominent spine on each side of the black thorax. The antennae are longer than the body and consist of 11 black segments with a white or whitish-blue base. The legs are black and have a bluish tinge.[1, 4, 38, 99]

HOST TREES

Acer, Aesculus, Albizia, Betula, Celtis, Platanus, Populus, Salix, Sorbus and *Ulmus* are host trees in North America.[1, 4, 38] The suitability of *Alnus, Crataegus, Elaeagnus, Fraxinus, Hibiscus, Malus, Morus, Prunus, Pyrus, Quercus, Robinia* and *Tilia* in North America is still in question.

LOCATION OF INFESTATION WITHIN THE TREE

Female beetles oviposit on exposed roots, along the entire bole and on branches as small as 2 to 3 cm in diameter.[4] Immature larvae feed on the inner bark and sapwood while mature larvae feed on the heartwood.[4, 38] Beetles feed on leaves, petioles, or the inner bark of twigs.[1, 38, 99]

HOST CONDITION

Healthy and weakened trees. Females do not oviposit on dead, debarked wood.[1]

DISTRIBUTION

China, Korea and Japan. Introduced and under eradication in New York, Chicago, New Jersey, Toronto, Bayern (Germany), Gien and Sainte Anne sur Brivet (France) and Braunau (Austria).[1, 4, 38]

SIGNS AND SYMPTOMS

Beetles feed on the leaves and twigs of host trees.[1, 4, 38, 99] Feeding damage on young shoots causes them to wither and die.[99]

Females chew oval oviposition niches (about 10 mm wide) and lay a single egg in the inner bark. Depending upon the tree species, the oviposition niches are initially reddish-brown but fade over time. Oviposition niches can occur from ground level up into the crown on branches that are at least 2 to 3 cm in diameter. Frothy, white sap may exude from recently created oviposition niches.[1, 4, 38] Over time, the sap ferments and stains the bark.

Young larvae feed within the inner bark and sapwood and can cause the bark to become concave.[38, 99] Mature larvae bore into the heartwood. Late instar galleries are initially perpendicular to the stem axis but gradually turn upwards and can reach lengths of 3.5 to 15 cm.[4] These winding larval galleries can eventually lead to tree mortality in heavily infested trees. Coarse, sawdust-like frass is expelled from the larval galleries and will occur in piles around the base of the tree or in branch forks.[4, 38] Adults emerge through the wood by chewing round exit holes 6 to 12 mm in diameter and expel large, coarse wood fibres on the ground.[1, 4, 99] Exit holes may be present anywhere on the larger above ground parts of the host, including branches, trunk, and exposed roots.[1, 4, 38, 99]

Leaf yellowing and wilting, pre-mature leaf drop, branch die-back and tree death are symptoms of advanced infestation.[1, 4, 99]

Adult *A. glabripennis* (20-35 mm long).
Note approximately 20 irregular white spots on each elytron.

Bark staining caused by fermented sap.

New *A. glabripennis* oviposition niches (10 mm wide).

Old (darker) and new (reddish-brown) oviposition niches of *A. glabripennis*.

Frothy, white sap exuding from recent *A. glabripennis* oviposition niches.

Circular *A. glabripennis* exit hole (6-12 mm wide).

Coarse frass expelled by larva of *A. glabripennis*.

Coleoptera: Cerambycidae

Callidiellum rufipenne (Motschulsky)

Smaller Japanese cedar longhorned beetle

IDENTIFICATION

Adult beetles are 6 to 14 mm long, 3 to 4 mm wide and have a slightly flattened body.[91] The head and thorax are brown with reddish-brown hairs.[91] The 1st antennal segment is black while the following segments are chestnut brown.[91] Male antennae are slightly longer than the body while those of the female are about two-thirds the body length.[8] Male elytra are usually black with metallic blue-violet or greenish reflections.[8, 91] Females typically have brownish-red to red elytra.[91]

HOST TREES

Chamaecyparis, Cryptomeria, Cupressus, Juniperus and *Thuja.*[1] The suitability of *Cedrus, Pinus* and *Abies* is still in question.[91] In North America, *C. rufipenne* has been found in *T. occidentalis, J. virginiana* and *J. communis*.[1, 90, 91, 92]

LOCATION OF INFESTATION WITHIN THE TREE

Larvae feed on inner bark and sapwood where the stem or branch diameter is at least 1 cm.[8, 90, 91]

HOST CONDITION

Preferentially attacks dying, weakened, stressed or freshly felled trees.[10, 90]

DISTRIBUTION

China, Japan, Korea and Russia (Sakhalin). Introduced into Italy, Spain and North America (Connecticut and North Carolina).[1, 20, 90, 91, 92]

SIGNS AND SYMPTOMS

Eggs are laid in bark crevices. Newly hatched larvae bore through the bark and construct shallow, flat and irregular shaped galleries (2 to 6 mm wide).[10, 91] Gentle scraping of the bark may be required to expose the frass-filled galleries.[91] These larval galleries increase in width as the larvae increase in size.[90] Mature larvae create an "L-shaped" gallery by boring straight into the sapwood, then construct 2.4 to 2.7 cm long pupation chambers parallel to the grain.[10, 91] The entrance to these pupal chambers is tightly packed with fine, powdery frass.[10] Adults emerge from elliptical exit holes that are 6 to 10 mm or more in diameter.[90]

Other signs of attack include bark depressions resulting from larval mining, light red frass on branches and the trunk, 8 to 15 mm long cracks in the bark, callus tissue (i.e. puckering) forming over the larval galleries and brittle branches that may crack and expose the larval galleries beneath.[9, 90, 91] Attacks can also hasten the death of the host tree or increase its susceptibility to pathogens or other forest insects.[91]

A

Adult *C. rufipenne*. Head and thorax are brown with reddish-brown hairs.

B

Male *C. rufipenne* has black to bluish-green elytra and longer antennae. Female has red elytra and shorter antennae.

C

Adult *C. rufipenne* ready to emerge from the pupal chamber.

D

Frass plug blocking the pupal chamber entrance.

E

Frass filled *C. rufipenne* larval galleries.

F

Callus tissue surrounding *C. rufipenne* galleries.

G

Elliptical *C. rufipenne* exit hole (6-10 mm wide).

Coleoptera: Cerambycidae

Cerambyx cerdo Linnaeus

Great Capricorn beetle

IDENTIFICATION

Adult beetles are 24 to 53 mm long, with a blackish body and legs.[25] Male antennae are twice as long as the body, while those of the female extend to the elytral apex.[25] The pronotum is roughly textured and greater in width than in length. The tapered elytra are reddish-brown towards the apex.[25] The elytral apex has well developed sutural spines.[128]

HOST TREES

Quercus (main host), *Carpinus, Castanea, Ceratonia, Fagus, Fraxinus, Juglans, Pyrus, Robinia, Salix* and *Ulmus*.[25, 85, 128]

LOCATION OF INFESTATION WITHIN THE TREE

Larvae feed on the inner bark, sapwood and heartwood along the stem.[25, 128]

HOST CONDITION

Mature, weakened (e.g. diseased, pruned) trees, especially those growing in open and sunny locations.[25, 85, 117, 128] Occasionally young or healthy trees are attacked.[85]

DISTRIBUTION

Europe, Asia, Caucasus, Asia Minor and northern Africa.[25, 121, 128]

SIGNS AND SYMPTOMS

Females lay eggs in the bark.[117] Larvae develop in the inner bark before penetrating into the sapwood, and then into the heartwood.[25, 117, 128] Larval galleries are long, irregular and widen as the larvae increase in size.[25, 117, 128] Larval development may take up to 2 to 5 years.[25, 117]

Pupation occurs in the sapwood (approximately 80 mm deep) in a large, elongate, oval pupal cell that is partitioned from the larval gallery by a calcareous operculum secreted by the larvae.[128] Adults overwinter in the pupal cell and emerge at the end of spring, during the summer, or at the beginning of fall.[25, 117] Exit holes are more or less oval and up to 2 cm in diameter. Brown frass also accumulates at the base of infested trees.

Dark resin seeps from holes at attack sites.[117] Several generations may develop in the trunk. Re-infestation may continue year after year, highly degrading the wood and in some cases causing death of the infested tree.[117, 128]

A

Male *C. cerdo* (24-53 mm long). Antennae are twice the body length.

B

Female *C. cerdo* (24-53 mm long). Antennae extend to the elytral apex.

C

Elongate and oval *C. cerdo* pupal chamber.

D

Adult *C. cerdo*. Elytra are reddish-brown towards the apex.

E

C. cerdo larval galleries within the sapwood.

F

Long, irregular-shaped *C. cerdo* larval galleries in the inner bark. Galleries widen as the larvae increase in size.

Coleoptera: Cerambycidae

Monochamus sartor (Fabricius)

IDENTIFICATION

These shiny, black metallic beetles are 21 to 35 mm long and have sparse yellow hairs on the elytra.[2, 25, 128] Antennae are twice the body length in males but only slightly longer than the body in females.[2] Antennae of both sexes are black but the bases of the 3rd to 11th antennal segments in females are whitish-gray.[2, 25]

A distinguishing characteristic of this species is a transverse saddle-like impression found behind the pronutum.[2] The pronotum and elytra of females have a few white spots, but these are absent or indistinct on males.[25] Female elytra have parallel edges whereas the male's narrows posteriorly.[2]

HOST TREES

Picea (main host), *Abies, Larix* and *Pinus*.[2, 25]

LOCATION OF INFESTATION WITHIN THE TREE

Larvae feed on the inner bark, sapwood and heartwood along the stem. Attacks usually occur 2 to 4 m above the ground.[2, 25, 85] Immature beetles maturation feed on needles, green cones and twigs.[2, 25, 128]

HOST CONDITION

Weakened, felled, fire scorched, or uprooted trees.[2, 25, 85, 128] Large diameter stems are preferred.[25, 85] As populations increase during an outbreak, attacks can occur on healthy trees.[2]

DISTRIBUTION

Europe.[2, 128]

SIGNS AND SYMPTOMS

Beetles emerge in spring and feed in the crown on needles, weakened twigs and green cones.[2, 85, 128] In the summer, fertilized females excavate a funnel-shaped pit in the bark, 6 to 7 mm wide and 4 to 5 mm long, and deposit a single egg in each niche.[2, 85, 128] At least 50 eggs are laid by a single female.[85]

Early instar larvae excavate large, deep, galleries (up to 50 cm long) packed with long, fibrous frass in the inner bark.[2] Through an oval entrance hole, larvae bore horizontal galleries into the sapwood that may sometimes reach the heartwood.[2, 128] Larvae then bore parallel to the grain of the wood for a few cm and expel frass through these holes.[2, 128] Last instar larvae mine "U-shaped" galleries, so that adult emergence occurs on the same side of the trunk as the entrance holes.[85, 128] Pupation chambers are plugged with wooden fibres and occur at a depth of 10 to 12 mm.[2] Adults emerge from exit holes 8 to 12 mm in diameter.[2, 128]

A

Adult *M. sartor* (21-35 mm long).

B

Male and female *M. sartor*. Male antennae are twice the body length. Female antennae are slightly longer than the body.

C

M. sartor larva and larval galleries (up to 50 cm long). Note long, fibrous frass in the larval galleries.

Coleoptera: Cerambycidae

Monochamus urussovi (Fischer)

Black fir sawyer beetle

IDENTIFICATION

Adult beetles are 18 to 37 mm long, with antennae that are 2 to 2.5 times the body length in males but only slightly longer than the body in females.[23, 25, 128]
The pronotum is as long as it is wide.[138]
The head and pronotum have sparse white or yellowish pubescence. Legs, elytra and antennae are all black with a very slight brass tinge, but female elytra also have spots of whitish-gray hairs.[25, 128, 138]

HOST TREES

Abies (most heavily damaged), *Larix, Picea* and *Pinus*.[25, 26, 137, 138] Even though this species is frequently found on *Betula*, it causes little damage to it.[26]

LOCATION OF INFESTATION WITHIN THE TREE

Immature beetles maturation feed on twigs, branches and needles within the crown.[25, 138]
Larvae breed in the inner bark and sapwood along the entire bole of standing trees. In felled trees, larvae primarily breed within the lower bole.[25, 128, 138]
Larger trees (16 to 40 cm in diameter) are preferentially attacked.[138]

HOST CONDITION

Breeding preferentially occurs in damaged (e.g. drought, fire, and windthrow), dying or recently cut trees.[25, 26, 50, 138] Outbreaks can occur in live healthy trees.[26] Beetles prefer to feed on young, thin growing shoots.[50, 138]

DISTRIBUTION

Europe, Russia, Japan, Korea, Mongolia and northern China.[25, 138]

SIGNS AND SYMPTOMS

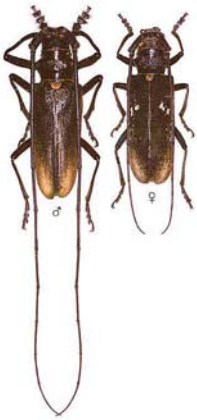
Beetles feed in the crown, removing strips of bark and infecting branches with spores of phytopathogenic *Ceratocystis* fungi.[26] The developing fungi kills branches on the periphery of the crown, weakens the tree, and reduces resin flow, thus making the tree suitable for oviposition and larval feeding.[26, 50, 138]

In the summer, fertilized females excavate oviposition niches and deposit a single egg beneath the bark.[2, 26] Larvae bore broad (2 to 2.5 cm wide), sinuous galleries beneath the bark that are filled with frass and fine chips.[2, 26, 138] Frass is expelled through ventilation holes along the gallery.[138] After overwintering, last instar larvae bore into the sapwood through an oval entrance hole that is on average 16 by 6.5 mm.[138] The excavation of these galleries is at first transverse, then longitudinal, exhibiting an almost 90 degree turn.[138] The longitudinal portion is often packed with a frass plug and ends in a pupal chamber (6.5 cm long and 2.0 cm wide).[138] Adults emerge through round exit holes that are 6 to 12 mm in diameter.[26, 138] As infested host trees die, needles fade from green to yellow and finally to red.[61]

A

Adult *M. urussovi* (18-37 mm long). Note brass tinge on elytra.

B



Male (antennae 2.0-2.5 times body length) and female (antennae slightly longer than body) *M. urussovi.*

C

Chlorotic needles on tree attacked by *M. urussovi*.

D

Circular *M. urussovi* exit hole (6-12 mm wide).

E

M. urussovi pupal chamber.

F

Broad (2-2.5 cm wide), sinuous *M. urussovi* larval galleries.

G

M. urussovi larval gallery leading to the pupal chamber.

Coleoptera: Cerambycidae

Oberea linearis (Linnaeus)

Hazelnut longhorned beetle

IDENTIFICATION

Adult beetles are 11 to 14.5 mm long and have yellow legs.[121, 128] The body is black, cylindrical and very long and narrow.[115, 121, 128] The antennae are shorter than the body.[128] The prothorax bulges slightly in the middle.[115]

HOST TREES

Corylus (main host), *Alnus, Carpinus, Juglans, Ostrya, Salix* and *Ulmus*.[25, 37, 115, 121, 128]

LOCATION OF INFESTATION WITHIN THE TREE

Larvae develop within one year old shoots and twigs.[25, 37, 115, 121, 128] Immature beetles maturation feed on leaves.[25, 121]

HOST CONDITION

Healthy trees.[85, 121, 128]

DISTRIBUTION

North and central Europe, Caucasus to Southern Russia, and Turkey.[37, 121, 128]

SIGNS AND SYMPTOMS

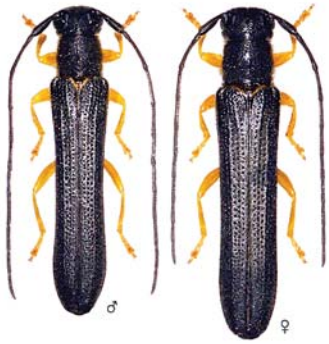
Beetles of this species feed on the lateral veins of young hazel leaves.[121]

Females chew through the bark, at the base of the previous year's branch, and deposit a single egg between the bark and sapwood.[37, 115, 128] Occasionally, adult beetles will girdle the shoot a few centimetres above the oviposition site.[37] Bark tissue around the egg becomes necrotic.[121]

Each larva bores to the central pith and mines a tunnel, 50 to 100 cm long, within the branch.[37, 115] Larval feeding causes the leaves to wilt, curl and turn brown and causes the shoot to break.[37] Crown damage is most noticeable in the fall.[37] In *Corylus*, shoot feeding also causes the bark to turn reddish.[37]

Larvae expel frass through ventilation holes along the twig so the tunnel remains hollow.[37, 115, 128] Larvae overwinter within the twig for 2 seasons.[37, 115] In the spring, last instar larvae make pupal chambers inside the base of the twig.[37, 115] The pupal cells are constructed by plugging off a section of the tunnel with two wads of fibrous frass.[128] The lower parts of pupal cells are filled with fine frass.[115] The pupal cells are 2.0 to 3.5 cm long.[115] Exit holes are oval (7.0 mm by 2.5 mm).[115]

A



Male and female *O. linearis* (11-14.5 mm long). Note yellow legs and black body.

B

O. linearis feeding on lateral vein.

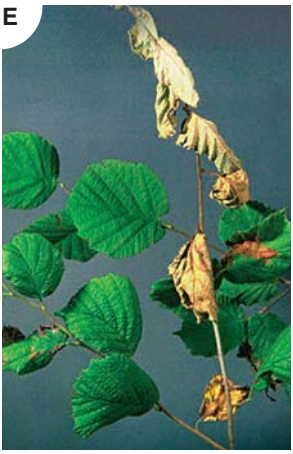
C

Maturation feeding of *O. linearis* on lateral veins of host leaf.

D

Necrotic tissue surrounding *O. linearis* oviposition niche.

E



Wilting foliage caused by *O. linearis* larva feeding within the branch.

F

O. linearis larva within larval gallery (50-100 cm long).

Coleoptera: Cerambycidae

Oberea oculata (Linnaeus)

Eyed longhorn beetle

IDENTIFICATION

Adult beetles are distinguished from other species of this genus by a comparatively large body (15 to 20 mm long), black head, elytra and antennae. The parallel elytra are covered with a fine ash-gray pubescence.[23, 25, 121, 128] The legs, pronotum, scutellum and ventral abdomen are rusty orange.[23, 25, 128] The antennae are shorter than their body and also taper from the base to the apex.[23, 128] Two (rarely 4) dark spots occur medially on the pronotum.[23, 128]

HOST TREES

Salix (main host) and *Populus*.[25, 121, 128]

LOCATION OF INFESTATION WITHIN THE TREE

Larvae infest living twigs, stems and branches 0.5 to 5 cm in diameter.[1, 25, 85, 121, 128, 131] Immature beetles maturation feed on leaves and young shoots.[23, 25, 128, 131]

HOST CONDITION

Healthy or recently dead hosts.[64, 85, 128]

DISTRIBUTION

Europe and Asia.[121, 128]

SIGNS AND SYMPTOMS

Immature beetles maturation feed on host leaves.[23, 128, 131] Longitudinal bite marks may be present and the leaf vein may be damaged.[23]

Females chew a small, longitudinal incision in the smooth bark of slender stems and twigs and lay a single egg.[23, 128] Bark tissue around these oviposition sites becomes callused and necrotic and the egg appears to be "enclosed in a chamber".[23]

After emerging from the eggs, larvae feed on the regenerative tissue near the oviposition site and cause dark spots to form on the bark.[23] After feeding in the callused area, larvae excavate straight longitudinal tunnels (36 to 50 cm long and 4 to 7 mm wide) in the central pith of twigs and branches.[23, 25, 85, 121, 128, 131] Ventilation holes occur at regular intervals and are used to discard frass and woodchips.[23, 131] Ejected frass accumulates on the twigs.[85]

Pupation occurs in the larval tunnels near the bark surface.[23, 85, 128, 131] Pupal cells, 4.5 cm long and 8 mm wide, are constructed by plugging off the upper and lower section of the chamber with two wads of coarse, fibrous frass.[23, 85] Shoots wither after 1 or 2 years of infestation.[23]

A

Adult *O. oculata* (15-20 mm long) with black head and antennae. Note orange pronotum, legs and abdomen.

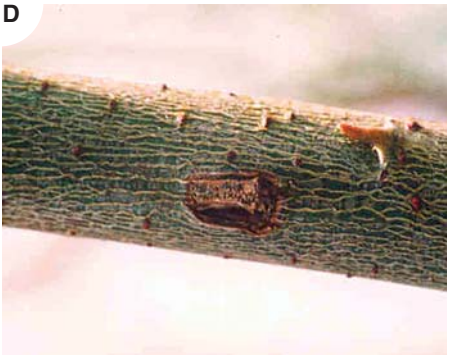
B

Ash-gray pubescence covering black elytra. Note 2 dark spots on orange pronotum.

C

O. oculata within larval gallery (36-50 cm long).

D



Callused and necrotic tissue surrounding *O. oculata* oviposition niche.

E

O. oculata larva.

Coleoptera: Cerambycidae

Plagionotus arcuatus (Linnaeus)

IDENTIFICATION

Adults are 8 to 20 mm long, with yellow-brown antennae and legs (front and middle legs have black femurs).[2, 25, 27, 128] The black pronotum is rounded laterally, has a yellow stripe on the anterior and posterior margins and has 2 oblique yellow stripes that converge near the middle.[2, 25, 27, 121] The antennae extend beyond the elytral midpoint in males and up to the midpoint in females.[27] Although colouration is variable, the elytra are typically black with yellow marks behind the scutellum and 5 to 6 transverse, thin, yellow bands.[27] The elytra are covered with dense, short brown or black hairs.[2, 27]

HOST TREES

Quercus (main host), *Acer, Carpinus, Castanea, Fagus, Prunus, Robinia, Salix* and *Tilia*.[1, 2, 25, 27, 121, 128]

LOCATION OF INFESTATION WITHIN THE TREE

Larvae feed on the inner bark and sapwood along the entire stem or in large branches.[121, 128]

HOST CONDITION

Prefers freshly felled trees or recently cut stumps, but can attack standing trees.[2, 27, 85, 121, 128]

DISTRIBUTION

Europe, Asia Minor, Syria and northern Africa.[2, 27, 128]

SIGNS AND SYMPTOMS

Eggs are laid in bark crevices.[2, 27, 128] Larvae mine frass-filled, longitudinal galleries beneath the bark on the main stem or branches. These galleries etch the inner bark and sapwood.[27] Larval galleries are 19 to 29 cm long and 10 to 45 mm wide.[27] Mature larvae bore into the sapwood for 1 to 3 cm at a 45 to 60 degree angle, and then mine galleries parallel to the grain of the wood.[27] The entrance hole to these galleries are 8 to 10 mm in diameter.[27] A pupal cell is formed at the end of these "L-shaped" galleries.[2, 27, 131] The entrance to the pupal cell is packed with fibrous frass.[85, 128] Larvae pupate on their backs, with their heads towards the bark.[85] Adults exit through oval emergence holes.

Larval feeding weakens standing trees and causes technical damage to the wood.[6]

A

Adult *P. arcuatus* (8-20 mm long). Note two oblique yellow stripes converging near middle of the pronotum.

B

Adult *P. arcuatus*. Note yellow-brown antennae and legs.

C

P. arcuatus pupal chamber. The entrance (8-10 mm wide) is packed with fibrous frass.

D

Adult *P. arcuatus*.

Coleoptera: Cerambycidae

Saperda carcharias (Linnaeus)

Large poplar longhorned beetle

IDENTIFICATION

Adult beetles are 20 to 30 mm long, yellow-brown, gray or gray-yellow and have an acutely pointed elytra.[25] The head and pronotum have numerous small black punctures, and the elytra have larger punctures.[25] Each elytron has a faint, indistinct, light-coloured transverse band below the midpoint.[25] Antennae are yellowish or gray with black apices and extend beyond the elytral apex in males, but do not reach the apex in females.[23, 25]

HOST TREES

Populus (main host), *Betula* and *Salix*.[23, 25, 32, 85]

LOCATION OF INFESTATION WITHIN THE TREE

Larvae feed on the inner bark, sapwood and heartwood.[2, 23, 85] They often attack the base of young trees and occasionally attack higher sections of larger stems and branches.[25] Immature beetles maturation feed on leaves and young shoots (1 to 2 mm diameter).[2, 23, 85]

HOST CONDITION

Healthy trees with a preference for hosts between 5 and 20 years old (3 to 30 cm in diameter).[23, 25, 85]

DISTRIBUTION

Europe, Korea and northern China.[2, 23, 25]

SIGNS AND SYMPTOMS

Immature beetles require supplementary feeding which mainly occurs on aspen and poplar but rarely on willow leaves.[23] Feeding usually occurs away from the leaf margin and is characterized by large oval or irregular shaped holes with serrated edges.[2, 23, 85] Usually the leaf veins and stems are consumed.[2, 85] Beetles also feed on the bark of young shoots and create pear-shaped incisions.[23]

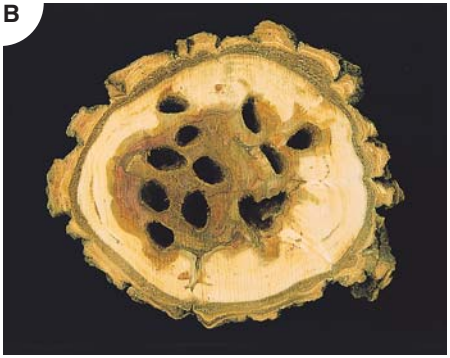
Prior to oviposition, females gnaw a vertical (occasionally oblique) incision, about 4.8 mm long, in the bark.[85] Females deposit one egg per niche, primarily on the basal part of the stem or on exposed roots.[2, 23] Each egg is covered with a sticky secretion.[85] First instar larvae excavate flat, 2.5 cm long galleries between the bark and sapwood.[2, 85] Later in the summer, older instars create "L-shaped" galleries by boring perpendicular to the sapwood and then vertically within the heartwood.[2, 85] These longitudinal galleries are 25 to 40 cm long and 12 mm wide.[23] A small ventilation hole is made in the upper part of the gallery. Coarse fibrous frass (large chips about 20 mm long) is discarded through the hole and accumulates in separate piles near the base of the tree.[2, 23]

Larvae hibernate 2 to 3 times prior to the construction of a pupal cell at the end of the "L-shaped" gallery.[23, 85] The pupal cell, 4.0 cm long and 1.5 cm wide, is isolated from the lower portion of the tunnel by a fibrous frass plug.[23] Pupae lie in cells with their heads pointing downward.[23] Severe infestations can directly cause tree mortality or predispose host trees to other mortality agents (e.g. fungi).[23]

A

Adult *S. carcharias* (20-30 mm long). Note acutely pointed elytra with numerous black punctures.

B



S. carcharias larval galleries within the heartwood.

C

Adult *S. carcharias*. Note yellow antennae with black apices.

D

Coarse fibrous frass expelled by *S. carcharias* larva.

E

Callus tissue and bark cracks caused by *S. carcharias*.

F

S. carcharias pupal chamber. Note fibrous frass plug.

G

S. carcharias larval gallery in the heartwood (25-40 cm long).

Coleoptera: Cerambycidae

Saperda perforata (Pallas)

IDENTIFICATION

Adults are yellow or grayish, slightly flattened dorsally and are 12 to 20 mm long.[23, 25, 121, 128] The pronotum typically has a single median spot as well as 8 black spots arranged into two transverse lines.[23, 25] Each elytron has a stripe of black pubescence along the shoulder, which extends towards the midpoint.[23, 25] Each elytron also has 5 black spots in a longitudinal line and a black spot on the basal quarter.[23, 25] Gray antennae have black apices.[2]

HOST TREES

Populus (main host) and *Salix*.[23, 25, 85, 121, 128]

LOCATION OF INFESTATION WITHIN THE TREE

Larvae feed on the inner bark and sapwood of stems and branches.[23, 25] Immature beetles maturation feed on leaves and thin shoots.[23, 25]

HOST CONDITION

Weakened, dying, recently felled or stressed trees.[23, 25, 121, 128] This beetle requires a very moist breeding substrate.[121] Larger diameter trees (18 to 35 cm in diameter) are preferred.[23, 25]

DISTRIBUTION

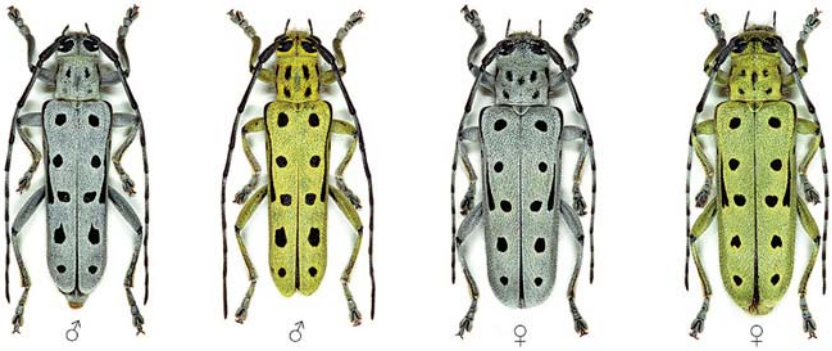
Europe and northern Asia.[2, 23, 25, 128]

SIGNS AND SYMPTOMS

Immature beetles feed on the tissues of green leaves and thin shoots.[23, 25] Prior to ovipostition, females gnaw small 3 mm incisions on the stem or branch and lay a single egg under the bark.[2, 23, 25] Larvae excavate irregular galleries in the inner bark that are packed with coarse fibrous frass.[2, 23, 25, 128]

Last instar larvae bore a 22 mm long horizontal gallery into the sapwood and then mine a longitudinal pupal chamber 21 to 27 mm long and 5 to 10 mm wide.[2, 25, 128] Larvae plug the pupal chambers with fibrous frass and pupate with their heads toward the entrance hole.[2, 25] Occasionally pupation takes place deeper in the sapwood due to desiccation of the outer sapwood.[128] Adults emerge through circular exit holes (6 mm in diameter).[2, 23]

A



Yellow and gray *S. perforata*. Note 5 black spots on each elytron.

B

Adult *S. perforata* (yellow morph).

C

Adult *S. perforata* (gray morph).

D

S. perforata in pupal chamber. Note fibrous frass plug.

E

Adult *S. perforata* (12-20 mm long).

Coleoptera: Cerambycidae

Tetropium castaneum (Linnaeus)

European spruce longhorn beetle

IDENTIFICATION

Adults are flat, 8 to 18 mm long, with antennae that are half the body length.[2, 19, 48] Adults typically have a black body, brown elytra, and either brown or red antennae and legs.[2, 48] The shiny pronotum is rarely punctured. The eyes are separated into two halves and a conspicuous longitudinal groove exists between the antennae on the head.[2, 48, 121] The elytra are uniformly covered with very fine hairs and are densely punctured.[2, 48]

HOST TREES

Picea (main host in Europe), *Pinus* (main host in Siberia), *Abies* and *Larix*.[2, 19, 42, 48, 128]

LOCATION OF INFESTATION WITHIN THE TREE

Larvae develop in the inner bark and outer sapwood from the roots upwards on the stem. However the lower bole is usually preferred.[2, 25, 48]

HOST CONDITION

Prefers freshly felled trees and stumps and trees weakened by drought, insects, fungi, air pollution, etc. However, healthy trees will also be attacked.[2, 19, 42, 48, 128, 131]

DISTRIBUTION

Europe and Asia (Siberia, Korea, Mongolia, China and Japan).[19, 42, 48]

SIGNS AND SYMPTOMS

Eggs are laid singly, or sometimes in clusters of up to 10 eggs, in bark crevices or under bark scales of host trees.[2, 42, 128]

Early instar larvae feed on the inner bark and outer sapwood.[128] Larvae excavate wide, irregular galleries that become densely filled with brown, granular frass.[2, 48, 128] Mature larvae bore horizontally (2 to 5 cm) into the sapwood through narrow elliptical holes.[2] Then larvae bore parallel to the grain for another 3 to 4 cm and form "L-shaped" galleries. At the end of these galleries, larvae form pupal chambers that are plugged with coarse white frass.[2, 19, 48, 128]

Pupae lie in a vertical position with their heads towards the frass plug.[48, 85, 131] In stumps, pupal cells are usually excavated in exposed roots or at the base.[128] Adults bore through the bark and emerge through oval exit holes that are 5 mm in diameter.[2, 19, 48]

Tetropium castaneum populations can build to levels where living trees are attacked and killed. The boring activity of the larvae can cause structural damage to the wood and may lead to stem breakage during windstorms. Copious resin flow occurs on attacked healthy trees.[48] The foliage of attacked trees can also fade from green to yellow and finally to reddish-brown.[42]

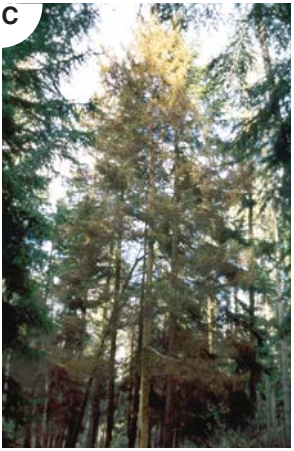
A

Adult *T. castaneum* (8-18 mm long).

B

Tree killed by *T. castaneum*. Note sloughing bark.

C



Yellowing foliage on attacked tree.

D

T. castaneum gallery filled with brown, granular frass. Note exit hole (5 mm wide).

E

T. castaneum larval galleries and exit holes (5 mm wide).

F

Irregularly shaped *T. castaneum* larval galleries.

G

Frass plug blocking pupal chamber entrance.

Coleoptera: Cerambycidae

Tetropium fuscum (Fabricius)

Brown spruce longhorn beetle

IDENTIFICATION

Adult beetles have a flattened body, 10 to 15 mm long.[1, 25, 55, 128] The head is black or dark brown, with a deep longitudinal groove between the antennae. The head is also covered with long, light-coloured hairs.[1, 25, 55] Their eyes are completely divided.[55] The slender antennae are half the length of the body and are reddish brown.[25, 55, 123, 128] The pronotum bulges laterally.[19] The elytra are tan, brown, or reddish-brown with 2 or 3 longitudinal grooves.[123] The legs are dark brown or reddish-brown.[1, 25, 55]

HOST TREES

Picea (main host), *Abies, Pinus* and *Larix*.[1, 25, 55, 128] In North America, only *Picea* has been found infested to date.[55]

LOCATION OF INFESTATION WITHIN THE TREE

Larvae feed on the inner bark and sapwood along the entire stem. However, the lower portions of the bole are the most heavily infested.[55, 123, 124]

HOST CONDITION

Stressed (e.g. drought, root disease), dying, recently felled, or healthy trees.[1, 25, 35, 55, 85] Middle aged and mature spruce trees are preferred.[124]

DISTRIBUTION

Europe and Japan. Introduced and under eradication in eastern Canada (Halifax, Nova Scotia).[1, 55]

SIGNS AND SYMPTOMS

Eggs are laid singly or in pairs in well concealed locations under bark scales or in bark crevices.[1, 55]

Larvae bore into the inner bark and excavate a network of irregular, 6 mm wide galleries, which become filled with tightly packed, fine-grained frass and short wood fibres.[1, 55] Larval galleries lightly etch the sapwood.[55] Much of the tree's inner bark can be destroyed by these wide, irregular and meandering larval galleries.[55] Mature larvae bore "L-shaped" galleries within the sapwood. Larvae first bore into the sapwood to a depth of about 2 to 4 cm, then turn parallel to the trunk for another 3 to 4 cm.[123] These galleries end in an oval-shaped pupal chamber.[1, 55]

Pupation occurs in the spring either in the bark, between the sapwood and bark or in the sapwood. Pupae lie in a vertical position with their heads pointed upward.[85] The wood may be stained from the associated *Ophiostoma* fungi.[55]

Adults exit through oval or circular exit holes that are 4 to 6 mm in diameter, which may or may not be plugged with coarse sawdust.[1, 55] Attacked trees produce excessive white resin down the length of the trunk.[55] Trees may be re-infested over subsequent years.[55] Infested tree crowns exhibit progressive yellowing, browning and loss of needles.[55] Once the tree has died, the remaining foliage changes to reddish-brown.[55]

A

Adult *T. fuscum* (10-15 mm long).

B

Resin flowing from tree attacked by *T. fuscum*.

C

Resin flowing from infested tree.

D

T. fuscum larva.

E

Irregular shaped *T. fuscum* larval galleries.

F

T. fuscum larval galleries and oval exit hole (4-6 mm wide). Note fine-grained frass in larval galleries.

G

Stand mortality caused by *T. fuscum*.

Coleoptera: Cerambycidae

Tetropium gracilicorne Reitter

Thin-antenna spruce borer

IDENTIFICATION

Adult beetles typically have a flat black body, 8 to 18 mm long, brown or red legs and relatively thin, short, brown or red antennae (half the length of body).[2, 19, 24] The 2nd through the 5th antennal segments are enlarged.[24] There are different colour morphs within this species: black body, antennae and legs with light brown elytra or completely black beetles.[19] The elytra have a broad covering of very fine hairs and are densely punctured.[2]

HOST TREES

Larix.[19]

LOCATION OF INFESTATION WITHIN THE TREE

Larvae feed on the inner bark and sapwood from root spurs to the top of the crown.[24]

HOST CONDITION

Stressed (e.g. defoliation, disease, fire, or wind), dying, and recently cut trees are preferred, but beetles also attack healthy, mature trees.[19, 24, 49] Trees of all ages are attacked.[24]

DISTRIBUTION

Asia including Russia, Kazakhstan, northern China, northern Japan and northern Mongolia.[24]

SIGNS AND SYMPTOMS

Female lays eggs, often in groups of 3 to 5 in bark crevices.[19, 24]

Larvae form irregular shaped, longitudinal galleries (10 mm wide) first in the inner bark and then later in the sapwood. Larval galleries are filled with granular frass.[19, 42] Mature larvae bore horizontally into the sapwood to a depth of 4 to 5 cm and then parallel to the wood grain for 1.6 to 2.2 cm.[19, 24] These "L-shaped" galleries end in a pupal chamber. If development occurs under thick bark, larvae may only bore beneath the bark without entering the sapwood.[24]

Before pupation, larvae make oval emergence holes that are plugged with frass.[24] Pupal chambers are lined with frass.[19, 24] Pupae develop with their heads toward the holes.[19]

Adults emerge through these oval holes.[19] External signs and symptoms include peeling bark, frass at the base of infested trees, beetles visible on the trunks, and yellowing and wilting of needles.[24] Consecutive years of attack can result in tree mortality.[42] When trees are not killed, infestations result in loss of vigor and reduced wood marketability due to bore holes.[24]

A

Adult *T. gracilicorne* (8-18 mm long). Note antennae are half the body length.

B

Close up of *T. gracilicorne* larva.

C

Start of L-shaped *T. gracilicorne* gallery in the sapwood.

Coleoptera: Cerambycidae

Xylotrechus altaicus Gebler

Altaï larch longhorn beetle

IDENTIFICATION

Adult beetles have an elongated (12 to 22 mm long), reddish-brown body.[4, 24, 27, 35] The head and thorax are black. The legs and antennae are reddish-brown.[4, 24, 27, 35] The antennae barely extend beyond the apex of the elytra.[27] The elytra are yellowish-brown and covered with dense short hairs.[4, 24, 27, 35] There are two or three barely visible, whitish bands crossing the centre of the elytra.[4, 24, 27, 35, 54]

HOST TREES

Larix.[4, 24, 35]

LOCATION OF INFESTATION WITHIN THE TREE

Larvae feed on the inner bark and sapwood over the entire length of the trunk.[4, 35, 54] Adult beetles are often found sitting on the trunks of host trees.[4, 27]

HOST CONDITION

Healthy or stressed trees are attacked. Mature trees are preferred but larch of all ages are susceptible to attack.[4] This insect is not known to attack felled (e.g. windthrow, cut logs), dying or dead trees.[4, 27, 35, 54]

DISTRIBUTION

Russia and Mongolia.[4, 24, 35]

SIGNS AND SYMPTOMS

Females usually attack hosts within 400 m of the tree in which they developed.[4] Eggs are laid singly in slit-like niches in the bark over the entire length of the trunk.[27] Oviposition usually occurs on the south-side of the trunk.[4, 35, 54]

Resin flows from wounds where young larvae have entered the bark.[4, 35] Early instar larvae feed on the inner bark.[4, 35] Larvae overwinter in the bark and in the spring they continue feeding on the inner bark, creating horizontal galleries (30 to 35 cm long and 10 to 13 mm wide) around the stem.[4, 27, 35] In the summer, larvae enter the sapwood to a depth of 1 to 10 cm and overwinter again.[27, 35]

The following spring, the larvae feed in the sapwood and gradually approach the bark surface.[4, 35] Mature larvae create pupal cells just under the bark (3 to 5 mm) and adults emerge from round exit holes, 4 to 6 mm in diameter.[4, 35] Frass is observed at the base of infested trees.[4]

Attacks can continue on the same tree for several consecutive years, ultimately causing its death.[4] Trees are eventually killed as the larvae encircle the inner bark and girdle the tree.[4] Needles of attacked trees often appear yellow or wilted.[35] When attacks on mature trees do not result in mortality, callus tissue encircles the larval galleries and the infestation causes a significant loss of vigour.[4, 27, 54]

A

Adult *X. altaicus* (12-22 mm long). Note yellowish-brown elytra, black head and thorax.

B

Adult *X. altaicus*.

Coleoptera: Cerambycidae

Xylotrechus rufilius Bates

IDENTIFICATION

The adult beetle differs from all other species in this genus by having a large, coarsely punctate, red pronotum and short elytra (length twice the total width).[27] Adults are 8 to 13 mm long.[27, 122] In males, the hind femora extend far beyond the elytral apex whereas in females the hind femora extend just beyond the apex.[27] The head and scutellum are black, while the antennae and legs are dark brown with a rusty tinge.[27]

HOST TREES

Acer, Ulmus and *Fraxinus*.[27]

LOCATION OF INFESTATION WITHIN THE TREE

Larvae feed on the inner bark and sapwood along the stem.[27]

HOST CONDITION

Dying and recently felled trees.[27]

DISTRIBUTION

Asian Russia, Japan, northeast China and Korea.[27]

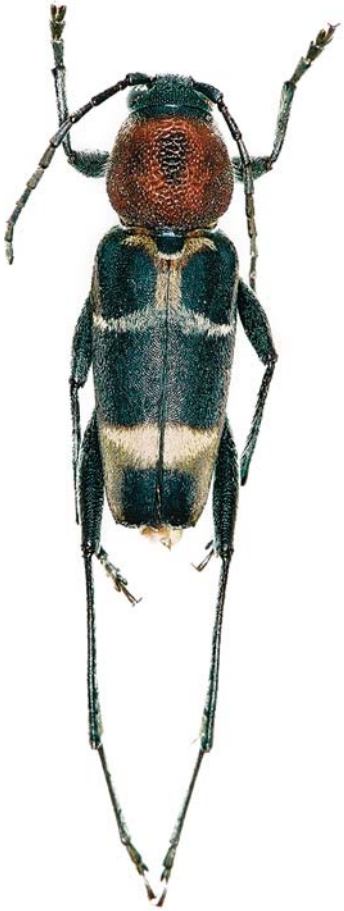
SIGNS AND SYMPTOMS

Females lay eggs singly or in batches within bark crevices.[27] Larvae bore through the bark and excavate longitudinal, meandering, frass-filled galleries.[27] Larval galleries may occasionally be transverse.[27] If eggs are laid in batches, larvae orient in different directions, leaving behind radial galleries in the inner bark.[27] The length of each larval gallery is approximately 28 cm, with an initial width of 1 mm and a terminal width of 12 mm.[27]

Some last instar larvae construct longitudinal pupal cells within the bark (a few millimetres beneath the bark surface).[27] Others bore into the wood, through 13 by 3 mm openings filled with frass, and create longitudinal pupal cells.[27] The pupal cells are 15 to 19 mm long and 5 to 7 mm wide.[27]

Larval feeding can girdle the tree causing a reduction in tree growth, crown stunting, wilting and branch mortality.[122]

A



Adult *X. rufilius*. Note large red pronotum and short elytra.

B

Adult *X. rufilius* (8-13 mm long).

Coleoptera: Curculionidae

Pissodes harcyniae (Herbst)

Spruce weevil

IDENTIFICATION

Adult weevils are black and 5 to 6 mm long.[2] Antennae are located along the middle of the adult's snout.[2] The posterior edges of the pronotum are rounded.[2] The elytra have two medial transverse yellow or white bands.[2]

HOST TREES

Picea.[2, 15]

LOCATION OF INFESTATION WITHIN THE TREE

Larvae feed on the inner bark and sapwood on the upper part of the stem.[2, 124] Immature beetles maturation feed on the inner bark of the stem where the bark is thin and smooth.[2]

HOST CONDITION

Diseased or weakened trees ranging from 50 to 100 years old are preferentially attacked.[2, 124]

DISTRIBUTION

Central and northern Europe, Siberia.[2, 15]

SIGNS AND SYMPTOMS

Immature beetles ascend the tree and feed on the inner bark of the stem.[2] Fertilized females excavate deep narrow holes into the bark of weakened trees and lay eggs individually or in groups of 2 to 5, creating a star-like gallery.[2]

Larval galleries are irregularly shaped and are initially 3 mm wide.[2] As they enlarge, they eventually intersperse with other galleries.[2] Larval galleries penetrate the inner bark but do not etch the sapwood.[2]

At the end of the larval galleries, mature larvae bore pupal cells, 7 to 10 mm long and 3 mm wide, that penetrate deep into the sapwood.[2] The pupal cells are lined with shredded wood.[2] Attacked trees appear wilted.[2]

A

Adult *P. harcyniae* (5-6 mm long).

B

Adult *P. harcyniae*. Note two yellow medial transverse bands on elytra.

C

P. harcyniae larval galleries ending in pupal chambers.

D

Irregular shaped *P. harcyniae* larval gallery widens as larva increases in size. Note shredded wood lining the pupal chamber.

E

Resin flowing from *P. harcyniae* maturation feeding sites.

F

Debarked boles of *P. harcyniae* attacked trees.

Hymenoptera: Siricidae

Sirex noctilio Fabricius

Sirex woodwasp

IDENTIFICATION

Adult wasps have four clear yellow membranous wings.[1, 22] Both sexes also have a stout, cylindrical body measuring 9 to 36 mm and a pointed abdomen.[1, 4, 22] Males have thickened, black hind legs and orange-yellow middle segments on the abdomen.[1, 4, 22] Females have reddish-brown legs and a steel-blue body.[1, 4, 22] Females also have a spike-like projection on their abdomen, which protects the ovipositor.[1, 4, 22]

HOST TREES

Pinus (main host), *Abies* and *Picea.*[1, 4, 22, 42]

LOCATION OF INFESTATION WITHIN THE TREE

Along the lower or middle portion of the bole, larvae feed on a symbiotic fungus within the sapwood and heartwood.[22, 59, 107, 113]

HOST CONDITION

Healthy and stressed trees (e.g. logging damage, drought, fire) or dead stems.[4, 105, 116, 131]

DISTRIBUTION

Europe, northern Africa, Mongolia, Siberia and Turkey. Introduced to Australia, New Zealand, South Africa, Argentina, Brazil, Uruguay and eastern North America.[1, 4, 22, 125]

SIGNS AND SYMPTOMS

Females use their saw-like ovipositor to cut oviposition holes 12 mm into the wood of the host tree.[1, 22, 131] Up to 5 holes are drilled into the outer sapwood.[22] The spores of a symbiotic white rot fungus (*Amylostereum areolatum*), which are fed upon by the larvae, and a toxic mucus are injected into the sapwood by ovipositing females.[1, 4, 22] Up to three eggs are laid per oviposition hole.[1, 4, 22] The fungus and the mucus act together to kill the tree and create a suitable environment for developing larvae.[4, 22, 110, 118] When the bark is removed, a dark fungal stain can be seen extending vertically from each oviposition site.[4, 114]

Larval galleries, 5 to 20 cm long, are packed with chewed wood and a fine powdery frass.[1, 4, 22] These galleries occur at all depths in the sapwood and heartwood, even to the centre of large trees.[1, 4] The length of the gallery and the size of the developing wasps are dependent upon the moisture content of the wood.[4] If the wood is dry, the galleries will be short, the smaller larvae will pupate earlier and become adults at a smaller size.[4] Mature larvae pupate close to the bark surface.[4] Adults emerge through circular emergence holes 3 to 8 mm in diameter.

Symptoms of attack also include beads of resin flowing from oviposition holes.[4, 59] Needles on attacked trees wilt and turn from green to yellow and finally to reddish-brown.[4] Stem growth is drastically reduced as a result of attack.[59] Mortality occurs in heavily infested trees.[4]

Male *S. noctilio*. Note black hind legs and orange-yellow middle segments on abdomen.

Female *S. noctilio*. Note brown legs and steel-blue body.

S. noctilio larval gallery (5-20 cm long). Note chewed wood lining the gallery.

Frass-filled *S. noctilio* larval galleries.

Circular *S. noctilio* exit holes (3-8 mm wide).

Resin flowing from *S. noctilio* oviposition holes.

Reddish-brown crowns on *S. noctilio* attacked trees.

Hymenoptera: Siricidae

Sirex rufiabdominis Xiao & Wu

Red-bodied horntail

IDENTIFICATION

Adult females are 18 to 34 mm long with black, 19 to 22 segmented antennae.[63] The wings are transparent on the basal half and smoky-brown on the apical half.[63] The body is covered with yellowish-gray hairs that are particularly abundant on the head and thorax.[63] Adult males are 14 to 22 mm long and their bodies are similar in colour to females but have more hairs.[63] Wings are pale yellow.[63]

HOST TREES

Pinus.[63]

LOCATION OF INFESTATION WITHIN THE TREE

Larvae feed on the sapwood and heartwood along the stem between the base of the tree and the main branches.[63] They are primarily found 2 m above ground level.[63]

HOST CONDITION

Weakened, stressed, or dying trees.[63] This insect prefers host trees growing in poorly sanitized or thinned forests or trees growing along the forest edge or on sunny slopes.[63]

DISTRIBUTION

China.[63, 119]

SIGNS AND SYMPTOMS

Females use their saw-like ovipositor to cut holes 1 mm into the sapwood.[63] At the time of oviposition, females first secrete a phytotoxic mucus (a colourless gel) that reduces the tree's ability to enclose the eggs.[63] One to seven eggs are laid per oviposition hole.[63] The browning and necrosis of the cambium that occurs around the phytotoxic mucus leads to wilting and tree mortality.[63]

Larvae initially bore 10 to 20 mm into the sapwood and create vertical galleries.[63] Late instar larvae then bore into the heartwood and may even reach the pith.[63] Galleries are winding (15 to 20 cm long) and filled with sawdust and small, hard frass pellets.[63] Most larvae return to the sapwood to pupate. Circular exit holes are 5 to 8 mm in diameter.[63]

A

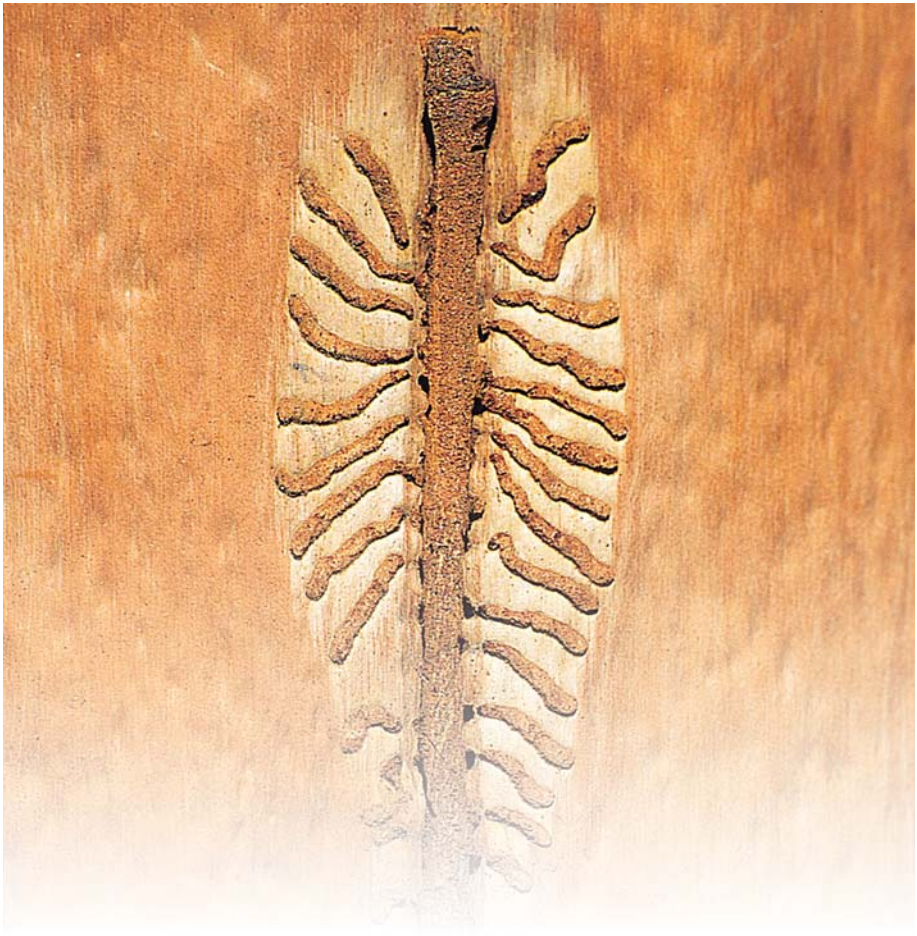
Adult *S. rufiabdominis* (18-34 mm long).

B

Frass-filled *S. rufiabdominis* larval galleries.

BARK BEETLES

- Scolytidae



Coleoptera: Scolytidae

Dendroctonus armandi Tsai & Li

Large pitch tube bark beetle

IDENTIFICATION

Adults are cylindrical beetles that are 3.5 to 6.8 mm long.[62] Newly emerged beetles are initially light-yellow but gradually become light-brown, black-brown and finally black upon maturation.[62]

HOST TREES

Pinus.[62, 101]

LOCATION OF INFESTATION WITHIN THE TREE

Larvae feed on the inner bark along the lower three-quarters of the bole.[62]

HOST CONDITION

Healthy or recently felled trees, greater than 30 years old are attacked.[62] Outbreaks generally initiate in pine forests growing in nutritionally poor, steep, dry sites, with thin soil layers.[62, 69] This insect prefers to attack trees growing in sparsely stocked forests and trees growing on southern aspects.[62]

DISTRIBUTION

Central China (Gansu, Henan, Hubei, Shaanxi, Sichuan and Yunnan provinces).[62, 69, 106]

SIGNS AND SYMPTOMS

Adult females mine monoramous, longitudinal egg galleries that are 10 to 60 cm long (30 to 40 cm average).[62] Females lay eggs in niches on both sides of the egg gallery.[62] The average distance between egg niches is 8 mm.[62] Larval galleries are perpendicular to the egg gallery and are usually 2 to 3 cm long, but may reach lengths up to 5 cm.[62] Elliptical pupal chambers are formed at the end of larval galleries.[62] Maturing beetles feed within the pupal chamber, greatly enlarging it and increasing the damage to the phloem tissue.[62]

Evidence of attack includes red to gray-brown pitch tubes (10 to 20 mm in diameter), reddish frass around entrance holes on the trunk, loose frass in bark crevices and fading of the foliage from yellow to yellow-brown.[62, 65, 67] Trees girdled by larvae will eventually die.[62]

A

Adult *D. armandi* (3.5-6.8 mm long).

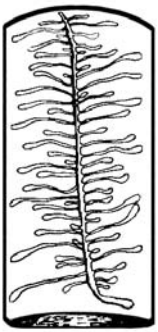
B

Pitch tubes on host tree attacked by *D. armandi*.

C

Pitch tube surrounding the entrance hole of *D. armandi*.

D



Drawing of *D. armandi* egg (10-60 cm long) and larval galleries (2-3 cm long).

Coleoptera: Scolytidae

Dendroctonus micans (Kugelann)

Great spruce bark beetle

IDENTIFICATION

Adult beetles are 5.5 to 9.0 mm long, 2.5 to 3.0 mm wide and are covered in orange hairs.[6, 60, 84] Adults are uniformly jet black or dark brown and cylindrical.[6, 84]

HOST TREES

Picea (main host), *Abies, Pinus, Larix* and *Pseudotsuga menziesii.*[4, 7, 24, 84]

LOCATION OF INFESTATION WITHIN THE TREE

Larvae feed on the inner bark.[6, 84] Attacks usually occur on the lower part of the bole, root collars and even on underground roots. However during outbreaks, galleries can also occur on branches in the upper crown.[60, 84]

HOST CONDITION

Preferentially attacks healthy trees but will also attack stressed trees (e.g. frost, snow, wind, drought).[4, 10, 14, 84] Usually prefers older, mature trees but can also attack younger age classes.[4, 84]

DISTRIBUTION

Europe, China, Japan, Mongolia and Turkey.[4, 24, 84]

SIGNS AND SYMPTOMS

Attacking females bore through the bark and create a narrow oblique groove-like egg gallery in which a group of eggs are oviposited.[60, 84] Pitch tubes surrounding the entrance hole and dried white resin may be visible on the trunk.[6] Pitch tubes may be purple, brown, cream or white and may be present individually or in a large group.[60] Granular resin at the base of the tree is also a good indication of attack. Within the egg gallery, early instar larvae feed side by side creating a widening feeding front beneath the bark.

As a result of gregarious larval feeding that occurs until pupation, the gallery system (cavity) often appears fan-like.[10, 84] Feeding occurs along a leading edge; islands of frass and dead individuals are left behind in the rectangular cavity from which the larvae started from.[6, 60, 84] These cavities are 30 to 60 cm long and 10 to 20 cm wide.[60] Pupation occurs within individual niches in the rectangular cavity.[60]

Red, powder-like frass is expelled from emergence holes and can be found in bark crevices along the trunk.[60] Foliage can turn brown over some of the crown (e.g. top kill) or over all of the crown, depending upon the severity of the attack.[60] Entire trees can be killed as a result of the girdling caused by feeding larvae. Trees that have undergone repeated attack will also have broken, peeling (bark peels as larvae consume inner bark), and often blackened bark.[4] However, some infested trees can retain a green canopy, even with severe girdling.[84]

A

Adult *D. micans* (5.5-9.0 mm long). Note orange hairs covering body.

B

Gregarious feeding of *D. micans* larvae.

C

Pitch tube and frass at the base of an attacked tree.

D

D. micans pitch tube surrounding the entrance hole.

E

Dried resin on attacked tree.

F

Declining *Picea* caused by *D. micans* attack.

G

Top kill caused by *D. micans*.

Coleoptera: Scolytidae

Hylastes ater (Paykull)

Black pine bark beetle

IDENTIFICATION

Adults are cylindrical and shiny black or slate gray with reddish-brown antennae and elytra.[4, 18] Adults are 3.5 to 5.0 mm long and 1.4 mm wide.[4, 18] Newly emerged beetles are uniformly reddish-brown but darken as they mature.[18] When viewed from above, a small portion of the head projects beyond the pronotum.[18] The head is directed downwards and is prolonged into a short snout.[18]

HOST TREES

Pinus (main host), *Araucaria, Abies, Larix, Picea, Pseudotsuga* and *Thuja.*[4, 18]

LOCATION OF INFESTATION WITHIN THE TREE

This species breeds primarily in the inner bark of roots, fresh stumps, the base of dead and dying trees or logs in contact with the ground.[4] However, immature beetles feed on the inner bark of pine, spruce, true firs, Douglas-fir and larch seedlings.[4]

HOST CONDITION

Breeding occurs in fresh stumps, recently dead or broken host material and dying trees.[4]

DISTRIBUTION

Europe.[4] Introduced into Chile, Japan, South Africa, Australia and New Zealand.[4, 18]

SIGNS AND SYMPTOMS

Immature beetles remove patches of bark and inner bark from seedlings at ground level.[4] This feeding can cause heavy mortality.[4] Seedlings that survive attack will show resin-encrusted wounds in the major roots and on the portion of the stem below ground.[18] Injured seedlings first appear wilted and sickly, then often turn bright red, with needles becoming hard and brittle.[4] Injured seedlings tend to appear in clumps near infested stumps or logs, but may also be found at considerable distances from breeding sites.[4] In addition to the damage caused by feeding, beetles can also vector several black stain root diseases.[4]

Adults prefer moist breeding habitats especially underground roots and the underside of logs that are in contact with the ground.[4] A reddish, sawdust-like frass is expelled from entrance holes when adults bore into the bark. Brood galleries consist of a short entrance tunnel leading to an oblique nuptial chamber.[4] From this chamber the female bores a uniramous gallery (8 to 13 cm long) that is packed with frass and is usually parallel with the grain of the wood.[4] However, any males that are present will clear debris from the central egg gallery.[4] Egg galleries reach but do not engrave the surface of the sapwood, except in small diameter material.[4, 18]

About 100 eggs are laid in individual niches along the walls of the egg gallery.[18] Larval galleries initially occur at right angles to the egg gallery, but eventually become random and ultimately obliterate both the early larval galleries and those made by the parents.[4, 18] Upon maturation of the brood, groups of about 40 (up to 120) beetles may be present in broad irregularly shaped communal galleries underneath the bark.[18]

A

Adult *H. ater* (3.5-5.0 mm long).

B

Maturation feeding by *H. ater* on seedlings. Note reddish foliage.

C

Black staining of root collar associated with *H. ater* attack.

D

H. ater egg galleries (8-13 cm long). Note frass packed vertical gallery.

E

Resin-encrusted wound caused by immature *H. ater* beetles.

F

Immature beetles within communal galleries under the bark.

G

Immature beetles feeding on the inner bark of a seedling.

Coleoptera: Scolytidae

Hylesinus varius (Fabricius)

Ash bark beetle

IDENTIFICATION

Adults are black and are 2.5 to 3.0 mm long.[2] Antennae have three segments and are club shaped.[2, 112] The antennae and tarsi are both reddish.[112] The pronotum is shorter than it is wide.[2, 112] The elytra are flattened, rounded, and have irregular light and dark coloured patches.[2] Long hairs exist along the edge of the elytra.[2]

HOST TREES

Fraxinus (main host), *Acer, Ailanthus, Carpinus, Corylus, Fagus, Juglans, Olea, Pinus, Pyrus, Quercus, Robinia, Syringa, Tilia* and *Ulmus.*[2, 112]

LOCATION OF INFESTATION WITHIN THE TREE

Larvae feed on the inner bark along the stem and branches.[2] Immature beetles maturation feed on the inner bark of host trees.[112]

HOST CONDITION

Freshly felled, weakened, or stressed (e.g. drought) trees.[2] This is an aggressive beetle that can also attack healthy trees.[2, 112] Prefers thin bark of young host trees.[112]

DISTRIBUTION

Europe, Turkey and northern Africa.[2, 112]

SIGNS AND SYMPTOMS

Immature beetles maturation feed on neighbouring trees (usually young trees), mining short galleries (20 mm long) in the bark.[2, 112] Gall-like swellings (callus tissue) form as a result of maturation feeding and grow larger as beetles continue to feed in the same spot.[2, 112] During outbreaks, feeding is so intense that the entire bark of a tree can be destroyed.[112]

Adults initiate attack by creating a "clamp-shaped" entrance tunnel. Adults then mine biramous, transverse egg galleries 7 to 10 cm long and 1.5 mm wide.[2, 112] The two arms of the egg galleries originate from a central nuptial chamber (connected to the entrance hole).[112] Larval galleries, 3 to 5 cm long, branch at right angles from the egg gallery and etch the sapwood.[2, 88] Larval galleries turn black over time.[112] Light coloured frass is present on the bark surface.[88] Pupation occurs at various depths in the sapwood.[2]

Growth loss (i.e. stunting) and mortality can occur, especially on young trees.[112] This beetle also vectors *Pseudomonas fraxini* and is suspected to facilitate infection by *Nectria galligena* (beech bark disease).[112]

Adult *H. varius* (2.5-3.0 mm long).

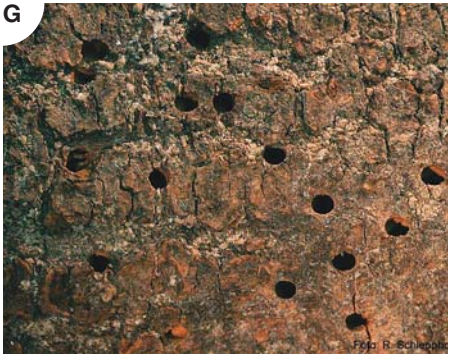
Callus tissue resulting from *H. varius* maturation feeding.

Light coloured frass from *H. varius* attack.

Callus tissue caused by maturation feeding.

H. varius egg and larval galleries.

H. varius egg and larval galleries. Note two-armed egg gallery extending from nuptial chamber.



H. varius exit holes.

Coleoptera: Scolytidae

Hylurgus ligniperda Fabricius

Red-haired pine bark beetle

IDENTIFICATION

Adults are small (4 to 6 mm long and 2 mm wide), cylindrical black-brown or golden-brown beetles.[4, 44, 93] The entire body is covered with dense yellowish or reddish hairs that are particularly noticeable on the posterior slope of the elytra and on the front of the head.[44, 93] The elytral apex is convex with a slight indentation but does not have teeth on the declivity.[82]

HOST TREES

Pinus.[44] *Pinus strobus, P. nigra* and *P. sylvestris* are known host trees occurring in Canada.[4, 93]

LOCATION OF INFESTATION WITHIN THE TREE

Larvae feed on the inner bark along the stem, roots and root collar.[44] In standing trees, females oviposit near the root collar.[93] These beetles will also attack buried logs or portions of the log in contact with the ground.[4, 93] Immature beetles maturation feed on the roots and root collar of healthy and stressed seedlings and young saplings (up to 15 cm in diameter).[93]

HOST CONDITION

Stressed or recently felled trees.[44] Females oviposit on freshly cut logs, stumps, slash and even seedlings.[44, 93]

DISTRIBUTION

Europe.[44, 93] Introduced into Brazil, Chile, Uruguay, Japan, South Africa, Sri Lanka, Australia, New Zealand and North America (near Rochester, New York).[44, 93]

SIGNS AND SYMPTOMS

Each female constructs a short entrance tunnel leading to an oblique nuptial chamber in the inner bark. From this nuptial chamber the female constructs a long egg gallery that usually runs parallel or at an angle with the grain of the wood.[4, 93] The egg gallery can be up to l m long and is not always straight; it often meanders and sometimes doubles back on itself.[4, 44, 93] Galleries may occur along the stem and in the roots and root collar.

The eggs are laid in notches cut in the walls of the egg gallery and are covered with frass. Egg galleries consist of alternating, 10 to 20 cm long sections with and without eggs. As a result, the larvae tend to be found in groups with mature or nearly mature larvae near the nuptial chamber, then groups of successively smaller, even-sized larvae at intervals along the gallery. The larval galleries are initially at right angles to the egg gallery but soon become random so that they make no distinctive pattern.[4, 44, 93]

As this insect tends to attack severely stressed or recently dead host material, pitch tubes and crown symptoms are usually not evident.[75] Along with the reddish brown frass found in bark crevices of host material, the presence of small, round exit holes and dark staining caused by associated fungi are other indications of attack.[93] Upon emergence, immature beetles seek pine hosts for maturation feeding and bore spiral galleries in seedlings and young saplings.[93] Mortality can occur if larger roots or the root collar of host trees are girdled.[93]

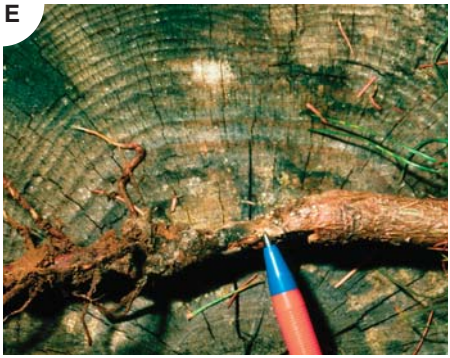
Hylurgus ligniperda has often been associated with many *Leptographium* species of varying pathogenicity. If these beetles vector a fungal pathogen, reduced height and branch growth, crown thinning, chlorosis and tree mortality may also be evident on standing infested trees.

Adult *H. ligniperda* (4-6 mm long). Note reddish hairs on the declivity and front of the head.

H. ligniperda egg gallery.

Numerous *H. ligniperda* adults under the bark.

Reddish-brown frass around stump attacked by *H. ligniperda*.



H. ligniperda maturation feeding damage on seedling.

H. ligniperda egg gallery (up to l m long) in stump.

Various life stages of *H. ligniperda*.

Coleoptera: Scolytidae

Ips hauseri Reitter

Hauser's engraver

IDENTIFICATION

Adult beetles are bright reddish-black, with an elongated body (3.5 to 5.0 mm long) and are completely covered with sparse, yellowish-brown hairs.[24] Each elytron has four spines along the declivity.[24] The 3rd spine in the male is finger-shaped and is the widest and longest, whereas in the female, the spines are all uniform.[24] The surface of the declivity is matted.[71]

HOST TREES

Picea, Larix and *Pinus.*[24]

LOCATION OF INFESTATION WITHIN THE TREE

Larvae feed on the inner bark along the entire bole, including the root collar, and in larger branches (inner bark and sapwood).[24] Immature beetles maturation feed on the inner bark of brood trees.[24]

HOST CONDITION

Healthy trees. But stressed, dying and recently cut trees are preferred.[24] Mature trees are preferred, but at high populations young trees (5 to 6 cm diameter) can also be attacked.[24]

DISTRIBUTION

Russia, Kazakhstan, Kyrgyzstan, Tajikistan, Turkey and China.[17, 42, 72, 73, 74]

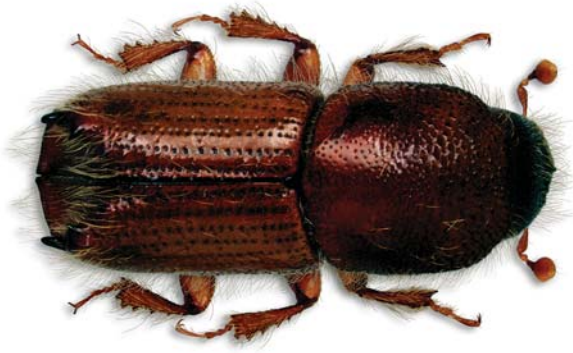
SIGNS AND SYMPTOMS

Immature beetles maturation feed under the bark of brood trees creating slightly irregular-shaped feeding galleries that are parallel to the main stem.[42] Adults emerge from small, round exit holes.[42]

One central nuptial chamber includes one male and 2 to 8 females.[24] Thus, several egg galleries can radiate downwards (most likely) or upwards from the nuptial chamber.[24] Longitudinal egg galleries are 8 to 14 cm long and 1.5 to 3.0 mm wide. These galleries are free of frass.[24] Females lay 20 to 45 eggs on both sides of the egg gallery.[42] The intervals between egg niches are shorter near the nuptial chamber than at the end of the egg gallery.[42]
The perpendicular larval galleries are short (3 to 4 cm long) and become wider as the larvae increase in size.[24, 42]

Symptoms of attack include resin flow from entrance holes, reddish-brown frass in bark crevices, pitch tubes and sparse crowns with partly dead tops and branches.[24, 42] Attack sites occur over the entire trunk from the top, down to the root collar.[24] Therefore, needles of attacked trees often show yellowing or reddening and wilting that usually begins at the top of a tree.[24]

A



Adult *I. hauseri* (3.5-5.0 mm long).

B

Elytral declivity of male *I. hauseri*. Note size and shape of 3rd spine.

C

Coleoptera: Scolytidae

Ips sexdentatus (Boerner)

Six-spined engraver beetle

IDENTIFICATION

Ips sexdentatus is the largest species in the genus *Ips*, measuring 5.5 to 8.2 mm in length.[4, 131] Adult beetles are dark brown and cylindrical.[4] The head is covered by a thoracic shield and the head is not visible when viewed dorsally.[4] Both sexes have six spines on each side of the declivity, of which the 4th is the largest and capitate.[24]

HOST TREES

Pinus (main host), *Abies, Larix, Picea* and *Pseudotsuga*.[4, 17]

LOCATION OF INFESTATION WITHIN THE TREE

Larvae feed on the inner bark of the lower bole.[132] This species prefers to attack larger trees with thick bark.[4, 66]

HOST CONDITION

This insect rarely attacks healthy vigorous hosts, preferring recently cut, weakened, dying or windthrown trees.[4, 77, 78, 131]

DISTRIBUTION

Europe, Asian Russia, Mongolia, China and Thailand.[4, 17, 24]

SIGNS AND SYMPTOMS

Males initiate the attack and create a large nuptial chamber beneath the bark.[4, 131] Males are joined by 2 to 5 females that create individual egg galleries, radiating longitudinally in opposite directions from the nuptial chamber.[4, 131, 132] Egg galleries are usually 15 to 35 cm long and 4 to 5 mm wide.[4, 131, 132] Eggs are deposited in individual niches along each side of the egg gallery.[4] Larval galleries run approximately perpendicular to the egg gallery and are 8 to 10 cm long.[4, 24, 132] Larval galleries increase in size as the larvae grow.[4] Both egg and larval galleries are mainly found in the inner bark and barely etch the sapwood.[131] Large round pupal chambers are located at the end of the larval galleries.[4, 131] Round exit holes on the bole, approximately 4 mm in diameter, will be apparent once adults emerge.[4]

Breeding attacks are characterized by the presence of reddish-brown frass on the bark surface of trees, freshly cut logs, or windthrow.[4] If relatively vigorous trees are attacked, pitch tubes can be found on the bole.[4, 127] The needles of attacked trees turn from green to yellow and then reddish-brown.[4] *Ips sexdentatus* acts as a vector for a bluestain fungus, *Ophiostoma brunneo-ciliatum*, which also damages the tree and stains the wood.[4, 24, 79]

A

Star shaped *I. sexdentatus* gallery system with six egg galleries radiating from the nuptial chamber.

B

Egg galleries (15-35 cm long) of *I. sexdentatus.*

F

Reddish-brown frass around the base of *I. sexdentatus* attacked tree.

G

Chlorotic foliage and woodpecker damage on *I. sexdentatus* attacked trees.

Coleoptera: Scolytidae

Ips subelongatus (Motschulsky)

Larch bark beetle

IDENTIFICATION

Adult beetles are completely brown and 4.5 to 6.0 mm long. Adults have four spines on each side of the elytral declivity.[24] The 3rd spine is the largest and is strongly capitate.[24] The surface of the elytral declivity is completely covered with long hairs.[24]

HOST TREES

Larix (main host), *Abies, Picea* and *Pinus.*[24, 26, 42]

LOCATION OF INFESTATION WITHIN THE TREE

Larvae feed in the inner bark along the length of the bole.[24] Immature beetles maturation feed in the inner bark of the bole and will feed in the root collar or branches if sites on the bole are unavailable.[24]

HOST CONDITION

Healthy, dying, stressed, or cut trees. Mature trees are preferred.[24]

DISTRIBUTION

Asian Russia, northern China and Mongolia.[24, 42]

SIGNS AND SYMPTOMS

Maturation feeding usually occurs along the trunk but may also occur on the root collar, the upper bole, or on branches.[24] These maturation galleries are filled with large quantities of frass.[24, 42]

Males initiate the attack and are joined by 2 to 5 females.[42] The shape and depth of egg galleries vary depending on host health, but all galleries originate from a central nuptial chamber.[24, 42] In healthy trees, egg galleries radiate downwards and upwards from the nuptial chamber, but in stressed hosts egg galleries radiate vertically and horizontally.[24, 42] Egg galleries are usually 3.0 to 3.5 mm wide and 16 to 18 cm long, but can reach lengths up to 27 cm.[24] Larval galleries are usually perpendicular to the egg galleries.[24] Pitch tubes and reddish frass occur on the bark surface.[42] Adults emerge from small round exit holes.[24, 42]

If the initial attack density is not too high, *I. subelongatus* usually re-attacks the same host tree over several consecutive years which can lead to the death of healthy trees.[24, 26] Additional symptoms of attack include sparse crowns, partly dead tops, wilting of needles, and fading of foliage from green to yellow and finally to red.[42] Resin also flows from entrance holes.[24]

A

Adult *I. subelongatus* declivity. Note the large and capitate 3rd spine.

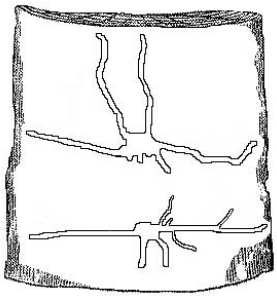
E

I. subelongatus egg and larval galleries.

F



I. subelongatus egg galleries on a stressed tree.

Coleoptera: Scolytidae

Ips typographus (Linnaeus)

European spruce bark beetle

IDENTIFICATION

Adults are 4.2 to 5.5 mm long, cylindrical and reddish or dark brown to completely black.[2, 4, 131, 136] The front of the head and the sides of the body are covered with long yellowish hairs.[1] Both sexes have four spines on each side of the elytral declivity, with the 3rd spine being the largest and capitate.[4] However, males have a larger head on the 3rd spine than do females and have fewer hairs on the pronotum.[2, 3, 97]

HOST TREES

Picea (main host), *Abies, Larix* and *Pinus.*[1, 4, 136]

LOCATION OF INFESTATION WITHIN THE TREE

Larvae feed in the inner bark up to 10 m along the stem.[35, 133, 136] This species prefers thicker-barked stems with a minimum bark thickness of 2.5 mm and an optimum thickness of 5.0 mm.[131, 134]

HOST CONDITION

This beetle prefers physiologically weakened, damaged, windthrown, recently felled or overmature trees.[4, 35, 133] However, as populations increase healthy hosts may be attacked.[4, 133] Infestations are more severe in stands greater than 120 years old, with a preference for trees between 70 and 150 years old. Stands less than 40 years old sustain very little damage.[4, 5, 35, 53]

DISTRIBUTION

Europe, China, Korea, Japan and Russia.[42]

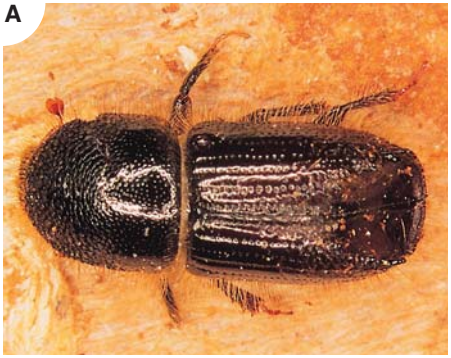
SIGNS AND SYMPTOMS

Males excavate a nuptial chamber and are joined by 1 to 4 females. Females construct egg galleries in the inner bark radiating outward from the nuptial chamber.[4] Vertical egg galleries are 10 to 20 cm long (12.5 cm average) and are usually three-armed, but can be two-armed or multi-branched.[1, 3, 88, 131] Approximately 50 eggs are laid on each side of the egg gallery.[3, 97, 136] Larval galleries radiate at right angles to the egg gallery and become wider as the larvae grow.[136]

On standing trees, needles turn yellow-green to red-brown and the foliage drops within a few weeks.[1, 136] Signs of infestation include red-brown frass in bark crevices, numerous round exit holes approximately 2 to 3 mm in diameter, and small (dime sized) tubes of resin (pitch tubes) extruding from the bark.[1, 136] Woodpecker damage may also be present.[6]

Adult beetles also carry a number of associated fungi such as *Ceratocystis polonica* (Siemaszko). This bluestain fungus is highly virulent and can kill healthy spruce trees.[4] This fungus also stains the wood with blue streaks, which reduces its commercial value.[4]

A



Adult *I. typographus* (4.2-5.5 mm long). Note yellow hairs covering head and body.

B

Brown frass around base of *I. typographus* attacked tree.

C

I. typographus egg (10-20 cm long) and larval galleries.

D

I. typographus egg and larval galleries. Galleries widen as larvae increase in size.

F

Stand mortality caused by *I. typographus*.

G

Reddish-brown frass at the base of tree attacked by *I. typographus.*

Coleoptera: Scolytidae

Pityogenes chalcographus (Linneaus)

Six-spined spruce bark beetle

IDENTIFICATION

Adult beetles are 1.6 to 2.9 mm long, and are either black or bicoloured (black head/thorax and red-brown elytra).[2, 82] The frons on males are flat, whereas the frons on females are round with a depression between the eyes.[2] Adults have a moderately excavated elytral declivity with 3 widely spaced conical teeth (per elytron) in males and 3 smaller rounded teeth in females.[2, 82]

HOST TREES

Picea, Larix, Pinus, Pseudotsuga menziesii.[28, 31] *Picea abies, Pinus sylvestris, Pinus strobus and Pseudotsuga menziesii* are known host trees occurring within Canada.

LOCATION OF INFESTATION WITHIN THE TREE

Larvae feed on the inner bark of stems and branches. On larger diameter trees, attacks initially occur high on the stem and subsequent attacks may occur progressively lower on the bole.[2, 97] Adults prefer to attack portions of the tree with thin bark.[29]

HOST CONDITION

Prefers stressed and recently felled trees (e.g. windthrow, uprooted trees) and logging residue (e.g. slash, stumps, broken tops). Populations can build up in these hosts and spill over into healthy trees.[28]

DISTRIBUTION

Europe, Siberia, Russia, Japan and China.[2, 15, 30]

SIGNS AND SYMPTOMS

Brownish-white frass, resulting from colonizing adult beetles can be observed in the bark crevices.[46] However, if attacks first occur high in the crown, frass will not be visible in the bark or at the base of the tree as it disperses during the fall from the canopy.[46] Streams of resin may exude from entrance holes, but these are not always readily observable within the crown.[46]

Pityogenes chalcographus galleries are stellate (star-like), usually with 3 to 6 egg galleries radiating from a central nuptial chamber. Each egg gallery is approximately 3 to 5 cm long and 1 mm wide.[2] Larval galleries are approximately 3 cm long, radiate away from the egg gallery in a more or less irregular pattern and may or may not penetrate the sapwood.[2] Larval galleries occur very close to each other and occur on both sides of the egg gallery.[2] Exit holes are small (less than 1 mm in diameter) and circular.[46]

On smaller (e.g. 2 to 4 m) trees, attacks occur along the entire length of the tree and crown symptoms (red needles) will be quite visible.[46] On larger trees, attacks initiate at the top of the crown and foliar colour change is not usually evident. In these trees the needles tend to fall to the ground, the crown appears thinned and the terminal leader will be dead.[46]

A

Adult *P. chalcographus*. Note elytral declivity with three widely spaced spines.

B

Reddish-brown crowns on *P. chalcographus* attacked saplings.

C

Egg (3-5 cm long) and larval (3 cm long) galleries of *P. chalcographus*.

D

Star shaped gallery system with egg galleries radiating from a central nuptial chamber.

E

P. chalcographus egg and larval galleries.

F

Top kill caused by *P. chalcographus*.

G

Chlorotic and thinning crown caused by *P. chalcographus*.

Coleoptera: Scolytidae

Scolytus intricatus (Ratzeburg)

European oak bark beetle

IDENTIFICATION

Adults are small brownish beetles measuring 2.4 to 4.0 mm.[4, 108, 109]

HOST TREES

Quercus (main host), *Aesculus, Betula, Carpinus, Castanea, Corylus, Fagus, Ostrya, Populus, Salix*, *Sorbus* and *Ulmus.*[4, 41, 102, 103, 104, 106, 108]

LOCATION OF INFESTATION WITHIN THE TREE

Larvae feed in the inner bark on the entire stem and in branches greater than 5 cm in diameter. Immature beetles maturation feed on twigs, usually at the juncture of the current year and 1 year old shoots.[4]

HOST CONDITION

Mature, recently dead, dying or stressed trees. Recently cut (less than 18 months old) logs and branches are also attacked.[4]

DISTRIBUTION

Europe, northern Africa and Asia Minor.[4, 103, 104]

SIGNS AND SYMPTOMS

Immature beetles fly to the crown and maturation feed on twigs, then seek breeding sites in trunks and branches.[100, 104] As a result of maturation feeding, broken shoots containing small entrance holes can be found on the ground beneath host trees.[40, 46]

Either males or females will bore through the bark and initiate construction of a transverse monoramous egg gallery.[41] These egg galleries are 5 to 20 mm long (11 mm average). Eggs are laid individually in regularly spaced niches along both sides of the egg gallery.[4] Larval galleries extend parallel to the grain (perpendicular to the egg gallery) and can reach lengths of 10 to 15 cm.[100] Larvae feed on the inner bark and slightly etch the sapwood.[41] During the first two instars, larval galleries remain discreet but gradually become indistinct as the larvae mature.[41] Exit holes are round and approximately 1.5 to 2.0 mm in diameter.[46]

Infested trees exhibit general symptoms of decline that include reduced growth, crown thinning (i.e. reduced foliage cover) and mortality.[4] Leaves generally do not change colour but usually shrivel and remain on the branch.[46]

A

Adult *S. intricatus* (2.4-4.0 mm long).

B

Transverse egg gallery (5-20 mm long) and vertical larval galleries (10-15 cm long).

C

Adult *S. intricatus*.

D

S. intricatus egg (transverse) and larval (vertical) galleries.

E

S. intricatus egg (transverse) and larval (vertical) galleries.

F

S. intricatus maturation feeding damage.

Coleoptera: Scolytidae

Scolytus morawitzi (Semenov)

Morawitz's bark beetle

IDENTIFICATION

Male beetles are 2.6 to 4.2 mm long while females are 3.1 to 4.8 mm.[24, 42]
The pronotum, antennae, and legs are all reddish-brown.[24, 42] Males have a retreating forehead.[24, 42] Females have a roughly wrinkled projecting forehead, covered with hairs which are denser on the lower part of the forehead.[24, 42] The length of the pronotum is greater than its width.[24, 42]
The abdomen of adults projects slightly beyond the elytra.[24, 42] The elytra are toothed near the apex and are furrowed.[24, 42]

HOST TREES

Larix.[17, 24]

LOCATION OF INFESTATION WITHIN THE TREE

Larvae feed on the inner bark along the stem and larger branches (7 mm diameter minimum) where the bark thickness does not exceed 3 to 4 cm.[24, 42] Immature beetles maturation feed on the inner bark of the stem and branches.[24, 42]

HOST CONDITION

Mature, stressed, dying or recently felled trees are preferred, but during outbreaks healthy trees of various ages are also attacked.[24] This species prefers to attack trees growing in sparse forests.[24]

DISTRIBUTION

Russia, Mongolia and northeast China.[17, 24]

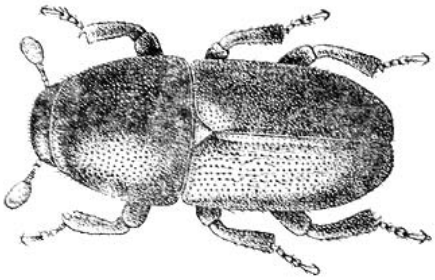
SIGNS AND SYMPTOMS

Immature beetles maturation feed at the top of the trunk and on branches.[24]
Adults bore 7 to 13 mm long galleries at these feeding sites.[24] These galleries can be distinguished from breeding sites by the absence of frass.[24]

The female adult bores under bark scales and creates a small central chamber where she initially lays 2 to 3 eggs.[24, 42]
As more eggs are laid the chamber is widened.[24] A total of 8 to 20 eggs are laid per chamber.[24, 42] Larval galleries are 15 to 17 cm long, radiate from the central chamber and may wind back and forth across other larval galleries.[24, 42] These galleries etch the sapwood and are filled with frass.[24] Larval galleries usually spiral around branches, encircling them.[24]
The ends of larval galleries are slightly enlarged to form pupal chambers.[24]
Adults emerge from small exit holes.

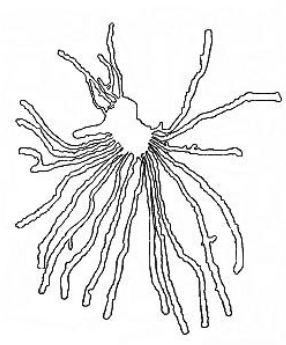
Resin and pitch tubes occur along the tree stem near the entrance holes.[24, 42]
Reddish-brown frass also occurs on the bark surface. The crowns of attacked trees are sparse with partly dead tops and branches.[24, 42] The foliage on infested trees often appears wilted and the needles usually fade from green to yellow.[24, 42]
This species usually re-attacks the same trees during several consecutive years causing their death.[24, 42]

A



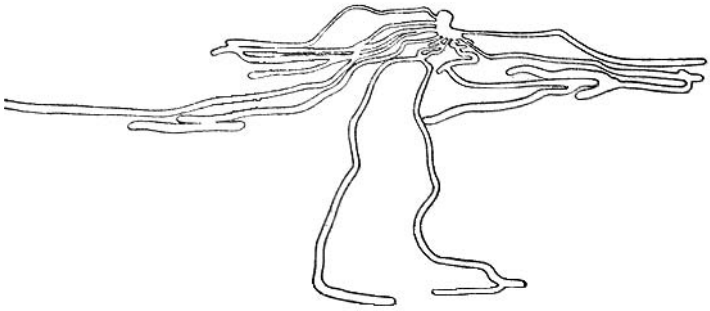
Adult *S. morawitzi* (2.6-4 mm long).

B



S. morawitzi larval galleries radiating from the nuptial chamber.

C



S. morawitzi larval galleries (15-17 mm long) radiating from the nuptial chamber.

Coleoptera: Scolytidae

Scolytus ratzeburgi Janson

Birch bark beetle

IDENTIFICATION

Adults are 4.5 to 6.5 mm, cylindrical, shiny black or brown.[2] Males have a long flat frons covered with dense hairs.[2] The pronotum is finely punctured.[2] Elytra are flat with punctured grooves and interstices, the posterior portions are smooth.[2] The legs and antennae are brown.[2]

HOST TREES

Betula and *Ulmus*.[2, 68]

LOCATION OF INFESTATION WITHIN THE TREE

Immature beetles maturation feed on bark, buds, leaves, and thin twigs in the crown.[68] Larvae usually develop beneath the thick, coarse bark of the main stem or large branches (less than 40 cm in diameter) but may occasionally develop in the smooth bark of smaller branches (5 to 7.5 cm in diameter).[68]

HOST CONDITION

Old and weakened trees. Healthy trees are attacked during outbreaks.[2]

DISTRIBUTION

Europe, Central and Eastern Russia, Mongolia and Japan.[17]

SIGNS AND SYMPTOMS

Immature beetles feed on fresh young twigs and branches of host trees.[68] They also feed on leaves but do not consume the leaf stalk.[68] Beetles bore a semi-circular gallery into the bark beneath the nodes.[68] These galleries are 1 to 2 cm long.[68] Callus tissue may occur over old maturation galleries.[68] In some cases galleries are not formed, but the bark is gnawed away in irregular patches.[68] Sometimes the maturation galleries are used as breeding sites. Otherwise, these galleries are abandoned and new ones are constructed for egg laying.[68]

Females initiate the attack. Entrance holes, shaped like the head of a golf club, are easily visible on smaller branches with thinner bark, but are difficult to find on thicker bark.[68] Females bore straight into the sapwood, then bore longitudinally along the axis of the bole. Reddish-brown frass is usually pushed out by females as they excavate the egg gallery.[68] Monoramous, longitudinal egg galleries are 0.75 to 10 cm long and etch the sapwood.[2, 68]

Eggs are laid in small niches on each side of the egg gallery and are packed with frass.[68, 131] At right angles to the egg galleries, long larval galleries (6 to 10 cm long) penetrate the sapwood as well as the bark.[2, 68, 89] As larvae grow the galleries approach the surface, with pupal chambers occurring just under the bark.[68]

Other signs of attack are the conspicuous ventilation holes in bark that are 2.5 mm in diameter.[2, 88] These holes are initially round, but become oval with use.[2] Dry crowns and die-back also occur on attacked trees.[2]

Scolytus ratzeburgi is associated with the occurrence of Dutch elm disease, facilitating the spread of this disease.[68]

A

Adult *S. ratzeburgi* (4.5-6.5 mm long).

B

S. ratzeburgi egg and larval galleries.

C

S. ratzeburgi egg (0.75-10 cm long) and larval (6-10 cm long) galleries.

D

S. ratzeburgi egg and larval galleries.

E

S. ratzeburgi ventilation holes (2.5 mm wide).

F

Dieback on *S. ratzeburgi* attacked tree.

Coleoptera: Scolytidae

Tomicus piniperda (Linnaeus)

Common pine shoot beetle

IDENTIFICATION

Adults are 3 to 5 mm long and cylindrical.[4, 131] Their head and thorax are shiny black while the elytra are reddish-brown to black.[6, 11] The head is visible from above. The elytral declivity is smooth and rounded.[4]

HOST TREES

Pinus (main host), *Abies, Larix, Picea* and *Pseudotsuga.*[4, 131]

LOCATION OF INFESTATION WITHIN THE TREE

Larvae feed on the inner bark along the bole from the root collar to the middle or lower crown. Immature beetles maturation feed and overwinter within shoots. Adults overwinter in short tunnels at the base of trees.[4, 66]

HOST CONDITION

Trees of all ages are attacked, with preference for larger standing brood trees (at least 12 cm in diameter). Dying, stressed (e.g. drought, defoliation, fire, snow) and healthy trees as well as recently cut stumps, felled trees and windthrow are preferred brood trees.[4, 66, 131] Shoot attack usually occurs above 1.8 m.[4, 12, 66]

DISTRIBUTION

Asia, northern Africa and Europe with introductions into eastern North America.[1, 4, 21, 33, 45, 51]

SIGNS AND SYMPTOMS

Breeding attacks are characterized by fine reddish-brown frass on the bark surface of trees. If relatively vigorous trees are attacked, whitish pitch tubes occur around entrance holes on the bark surface.[4] Adult beetles are associated with various species of blue stain fungi, which stain the sapwood.[4]

Females construct individual monoramous, vertical (more or less) egg galleries within the inner bark that are 10 to 25 cm long and about 2 mm wide.[4, 131] Females lay eggs singly in niches on both sides of the egg gallery.[4] This species periodically sweeps its egg galleries clean of frass.[52] Larvae construct galleries, 4 to 9 cm long, that are perpendicular to the egg gallery.[4, 131]

Immature beetles bore through the outer bark, creating round exit holes about 2 mm in diameter.[4, 51] Beetles then fly to the crowns of live, healthy pines of all ages and usually maturation feed on the current year's shoots.[4, 131] Beetles tunnel into the centre and bore outwards, hollowing out 2 to 10 cm of the shoot.[4] Shoot feeding does not kill the tree but causes reductions in height, diameter and volume.[4, 135] Damaged shoots display a round entrance hole (2 mm) and either one hollowed gallery or several short hollow galleries, which are usually surrounded by pitch.[1] Damaged shoots are disfigured, turn yellow then red, droop, become dry and brittle, and eventually break off near the entrance hole.[1, 4, 12, 131] After windstorms, branches break off and the tree appears pruned.[6]

In late October to November the adult beetles move down the tree to the base of the trunk where they bore into the bark to overwinter.[1, 131]

A

Adult *T. piniperda* (3-5 mm long) tunnelling in a shoot.

B

T. piniperda egg (10-25 cm long) and larval (4-9 cm long) galleries. Note vertical orientation of egg galleries.

C

Pitch tube surrounding entrance hole on brood tree.

D

Round entrance hole (2 mm wide) on infested shoot.

E

Green flagging on shoot caused by maturation feeding.

F

Frass expelled from *T. piniperda* entrance holes.

G

Red flagging caused by maturation feeding within current year's shoot.

Glossary

Abdomen: The region of the insect body behind the thorax. The last of the three major body divisions of an insect.

Abies: A genus of trees collectively known as true firs.

Acer: A genus of trees collectively known as maple.

Aesculus: A genus of trees collectively known as buckeye or horsechestnut.

Ailanthus: A genus of trees collectively known as Chinese-sumac or Tree-of-heaven.

Alnus: A genus of trees collectively known as alder.

Ambrosia beetle: Scolytids in which larvae feed on fungi lining larval galleries created within the wood of a tree. e.g. *Xyleborus* spp., *Xylosandrus* spp., *Trypodendron* spp.

Amygdalus: A genus of trees collectively known as almonds.

Antenna, antennae (pl.): A pair of segmented sensory organs located on the head of an insect, above the mouthparts.

Betula: A genus of trees collectively known as birch.

Bipectinate: Feathery, with branches on both sides of the main axis; applied mainly to antennae.

Biramous gallery: A system in which two egg galleries arise from the same nuptial chamber. Galleries can be longitudinal, transverse or diagonal.

Bole: The trunk or stem of a tree.

Buprestidae: A family of beetles known as flat-headed or metallic wood borers. Adults tend to be almond shaped and the larvae tend to have flattened heads.

Callus: An isolated thickening of tissue, usually developed by a plant to contain and isolate an infection or wound.

Cambium (vascular): In woody plants it is the single layer of cells between the bark and wood, from which new wood develops. Division of these cells results in diameter growth of the tree through formation of xylem and phloem.

Capitate: Abruptly enlarged and globular at the tip.

Carpinus: A genus of trees collectively known as hornbeam.

Carya: A genus of trees collectively known as hickory.

Castanea: A genus of trees collectively known as chestnut.

Cedrus: A genus of trees collectively known as true cedars.

Celtis: A genus of trees collectively known as hackberry.

Cerambycidae: A family of beetles known as longhorn beetles. Cerambycids that attack trees are also known as round headed wood borers. Adults usually have long antennae while the larvae are often cylindrical.

Chamaecyparis: A genus of trees collectively known as false cypress or yellow cedar.

Chlorosis: Abnormal condition characterized by the absence of green pigments in plants.

Coniferophagous: Organisms that feed on coniferous trees.

Coniferous tree: Commonly known as evergreen trees. Generally these trees retain their needles throughout the year, with the exception of larch. Also known as gymnosperms; woody vascular plants that produce naked seeds not enclosed in an ovary.

e.g. pines, spruces, true firs, Douglas-fir, hemlocks, cedars, junipers, cypress.

Corylus: A genus of trees collectively known as hazelnut.

Crataegus: A genus of trees collectively known as hawthorns.

Crown: The live branches and foliage at the top of a tree.

Cryptomeria: A genus of trees collectively known as Japanese-cedar or Sugi.

Cupressus: A genus of trees collectively known as cypress.

Curculionidae: A family of beetles known as weevils. Adults are snout nosed with their antennae located mid-length on the snout.

e.g. *Pissodes picea*, *Hylobius abietis*

Declivity: Posterior portion of the elytra that descends to the apex.

Deciduous tree: Commonly known as broad-leaved or hardwood trees. Generally these trees lose their leaves (except arbutus and holly) during the fall when the photoperiod decreases in intensity and duration (less light). They belong to a class of vascular plants known as angiosperms that have their ovules and seeds enclosed in an ovary.

e.g. oak, elm, ash, maple, hickory, alder, birch, arbutus, dogwood, beech, poplar, walnut.

Defoliators: Insects that feed on the needles or leaves of coniferous or deciduous trees. Major forest defoliators include budworms (Tortricids), tussock moths (Lymantriids), loopers or inchworms (Geometrids), sawflies (Diprionids), leaf beetles (Chrysomelids) and tent caterpillars (Lasiocampids).

Egg/parent gallery: The gallery produced by an adult beetle in which eggs are laid. It is from the egg or parent gallery that larval galleries will initiate.

Elaeagnus: A genus of trees collectively known as oleasters.

Elytral declivity: Posterior portion of the elytra that descends to the apex.

Elytral suture: The area on the dorsal side of a beetle where the two elytra meet.

Elytron; elytra (pl): The thickened, sclerotized forewings of insects such as beetles.

Epicormic branches: Adventitious twigs or branches that form from dormant buds along the bole or branches. These branches usually form in response to tree stress.

Epistoma: The region on an insect's face above the mouthparts and below the frons. In many beetles, the mouthparts articulate with this region.

Exit hole: A hole through the bark or wood that is created by an emerging insect.

Fagus: A genus of trees collectively known as beech.

Forewing: The first or anterior pair of insect wings.

Frass: The waste material produced by feeding insects that includes excrement and partially chewed vegetation.

Fraxinus: A genus of trees collectively known as ash.

Frons: Upper part of the insect face, between the eyes and above the epistoma.

Genus, genera (pl.): A group of evolutionarily related species, sharing one or a number of characteristics.

Hair pencil: The collection or mass of elongate hairs (i.e. setae) growing from the integument of an insect.

Head: The anterior region of an insect, which bears the mouthparts, eyes and antennae.

Heartwood: The inner core of a woody stem composed of nonliving cells and usually differentiated from the outer wood layer (sapwood) by its darker colour.

Hibernaculum; hibernacula (pl.): A shelter occupied during winter by a dormant animal.

Hindwings: The second pair of wings of an insect.

Infestation: A term generally used to define large, extensive forest insect populations. Similar in definition to an outbreak.

Inner bark: The living tissue beneath the outer bark. Also known as phloem.

Instar: The stage of an insect's life between successive molts, for example the first instar is the stage between emergence from the egg and the first molt.

Juglans: A genus of trees collectively known as walnut.

Juniperus: A genus of trees collectively known as junipers.

Large wood borers: A term used in this book to describe cerambycids, buprestids, weevils and siricids.

Larix: A genus of trees collectively known as larch.

Larva, larvae (pl.): The immature stage between the egg and pupa of insects having complete metamorphosis where the immature differs radically from the adult (e.g. caterpillars, grubs).

Larval gallery: The galleries produced by the mining action of larvae. Larval galleries initiate from egg/parent galleries.

Lasiocampidae: A family of lepidoptera known as tent caterpillars.

Lepidoptera: An order of insects that includes butterflies and moths.

Lymantriidae: A family of lepidoptera known as tussock moths.

Malus: A genus of trees collectively known as apple.

Maturation feeding: Some forest insects require supplemental feeding, before or after emerging from the host, to complete sexual maturation and sclerotization (hardening and darkening of the cuticle) or to increase energy reserves.

Monoramous (uniramous) gallery: A linear, non-branching egg gallery that can be either transverse or parallel to the wood grain.

***Morus*:** A genus of trees collectively known as mulberry.

Naturalized: An organism that has been introduced into a new environment and has become established as if it was indigenous to this area.

Necrosis: A pathological state characterized by brown or dark discoloration and disintegration (local tissue mortality) of plant tissue.

Nuptial chamber: For bark beetles and woodborers it is usually a small gallery beneath the bark in which mating occurs.

Oblate: Flattened or depressed at the poles (e.g. oblate spheroid).

Olea: A genus of trees collectively known as olives.

Order: A taxonomic subdivision that contains groups of related families or superfamilies. Order names usually end with a "-ptera" in insects.

Ostrya: A genus of trees collectively known as hop-hornbeam or ironwood.

Outbreak: A term generally used to define forest insect populations that are extensively and intensively large. Usually populations increase dramatically resulting in mortality or defoliation over a large area (> 1 ha).

Overwinter: A period of rest or hibernation by which insects survive the winter.

Oviposition: The laying or depositing of eggs.

Ovipositor: The tubular or valved egg-laying apparatus at the posterior end of a female insect.

Pathway: The way in which an organism is moved to a new environment.

Pectinate: Having branches which arise from the main axis like the teeth of a comb; usually applied to antennae.

Phloem: The tissue in the conducting system of a plant through which metabolites (products of chemical reactions in the plant, such as sugars) are transported.

Phytotoxic: Poisonous to plants.

Picea: A genus of trees collectively known as spruce.

Pinus: A genus of trees collectively known as pine.

Pitch tubes: Usually a tubular mass of resin that forms on the surface of bark at entrance holes.

Platanus: A genus of trees collectively known as sycamore.

Populus: A genus of trees collectively known as aspen, poplar or cottonwood.

Pronotum: The dorsal surface or sclerite of the 1st thoracic segment, located just behind the head of an insect.

Prunus: A genus of trees collectively known as cherry or plum.

Pseudotsuga: A genus of trees of within the pine family which is collectively known as Douglas-fir. This genus is closely related to *Larix* and is native to Canada, U.S.A., Mexico, Japan and China.

Pterocarya: A genus of trees collectively known as Asiatic nut or Chinese wingnut.

Punctate: Marked by minute depressions.

Pupa, pupae (pl.): For insects with complete metamorphosis, it is the nonfeeding stage between the larva and adult.

Pyrus: A genus of trees collectively known as pear.

Quarantine pest: A pest of potential economic importance to the area endangered thereby and not yet present there, or present but not widely distributed and being officially controlled, (IPPC).

Quercus: A genus of trees collectively known as oak.

Root collar: The transition zone between stem and root at the ground line of a tree or seedling.

Robinia: A genus of trees collectively known as locust.

Rosa: A genus of erect or climbing shrubs collectively known as roses.

Rubus: A large genus of brambles that produce berries (e.g. blackberry, thimbleberry, raspberry, etc.).

Salix: A genus of trees collectively known as willow.

Sapwood: The wood found closest to the bark and usually distinguished from heartwood by being lighter in color. Consists of xylem (structural support, transports water, etc.).

Scolytidae: A family of beetles known as bark beetles. Includes the true bark beetles in which the larvae feed on the phloem and sapwood and ambrosia beetles that feed on fungi within the wood of a tree.

Scutellum: A more or less triangular sclerite that occurs on the dorsal surface of the thorax, behind the pronotum.

Semiochemical: A chemical produced by on organism that affects the behaviour of another organism. Semiochemicals are used to detect and monitor exotic insects.

Siricidae: A family of wood boring wasps collectively known as wood wasps or horntails.

Small wood borers: A term used to describe ambrosia beetles.

Species: A group of individuals similar in structure and capable of interbreeding and producing fertile offspring.

Sorbus: A genus of trees collectively known as mountain ash, Rowan trees or dogberries.

Stellate: Arranged like rays or radiating from a common centre (i.e. star-like).

Sternite: Ventral segments of an insect's abdomen.

Stylet: A needle-like structure.

Syringa: A genus of shrubs collectively known as lilacs or mock-orange.

Terminal leader: The apical or uppermost vertical shoot on a conifer.

Thorax: The insect body region behind the head which bears the legs and wings. The middle of the three major divisions of the insect body.

Thuja: A genus of trees collectively known as cedar.

Tilia: A genus of trees collectively known as linden or basswood.

Tortricidae: A family of lepidoptera in which species that feed on trees are generally referred to as budworms or leafrollers.

True bark beetles: Scolytidae in which the larvae feed directly beneath the bark.

e.g. *Ips typographus*, *Pityogenes chalcographus*, *Hylurgus ligniperda*, *Hylurgops palliatus*.

Tsuga: A genus of trees collectively known as hemlock.

Tubercle: Small knobby protuberance or lump on the surface of an organism.

Ulmus: A genus of trees collectively known as elm.

Uniramous (monoramous) gallery: A linear, non-branching egg gallery that can be either transverse or parallel to the wood grain.

Variegated: Having discrete markings of different colours.

Windthrow: A tree or group of trees uprooted by the wind. Also known as blowdown.

Xylem: Woody tissue in vascular plants that provides support and carries water and nutrients up from the roots.

Host–Insect Index

Host	Insect	Position within tree
Abies	*Choristoneura murinana*	Crown (foliage)
	Dendroctonus micans	Root, Root Collar, Bole, Crown (branches)
	Dendrolimus sibiricus	Crown (foliage)
	Hylastes ater	Root, Bole
	Ips sexdentatus	Bole
	Ips subelongatus	Root Collar, Bole, Crown (branches)
	Ips typographus	Bole
	Lymantria monacha	Crown (foliage)
	Monochamus sartor	Bole, Crown (branches)
	Monochamus urussovi	Bole, Crown (branches & foliage)
	Sirex noctilio	Bole
	Tetropium castaneum	Bole
	Tetropium fuscum	Bole
	Tetropium gracilicorne	Bole
	Tomicus piniperda	Bole, Crown (foliage)
Acer	*Anoplophora glabripennis*	Root, Bole, Crown (branches & foliage)
	Calliteara pudibunda	Crown (foliage)
	Hylesinus varius	Bole, Crown (branches)
	Lymantria dispar	Crown (foliage)
	Lymantria monacha	Crown (foliage)
	Malacosoma neustria	Crown (foliage)
	Plagionotus arcuatus	Bole, Crown (branches)
	Tortrix viridana	Crown (foliage)
	Xylotrechus rufilius	Bole
Aesculus	*Anoplophora glabripennis*	Root, Bole, Crown (branches & foliage)
	Calliteara pudibunda	Crown (foliage)
	Scolytus intricatus	Bole, Crown (branches)
Ailanthus	*Hylesinus varius*	Bole, Crown (branches)
Albizia	*Anoplophora glabripennis*	Root, Bole, Crown (branches & foliage)
Alnus	*Lymantria dispar*	Crown (foliage)
	Malacosoma neustria	Crown (foliage)
	Oberea linearis	Crown (branches & foliage)

Insect–Host Index

Insect	Host	Position within tree
Agrilus biguttatus	*Castanea, Fagus, Quercus*	Bole, Crown (branches & foliage)
Agrilus planipennis	*Fraxinus, Juglans, Pterocarya, Ulmus*	Bole, Crown (branches & foliage)
Anoplophora glabripennis	*Acer, Aesculus, Albizia, Betula, Celtis, Platanus, Populus, Salix, Sorbus, Ulmus*	Root, Bole, Crown (branches & foliage)
Callidiellum rufipenne	*Chamaecyparis, Cryptomeria, Cupressus, Juniperus, Thuja*	Bole, Crown (branches)
Calliteara pudibunda	*Acer, Aesculus, Betula, Carpinus, Castanea, Corylus, Fagus, Juglans, Quercus, Populus, Salix, Sorbus, Tilia, Ulmus*	Crown (foliage)
Cerambyx cerdo	*Carpinus, Castanea, Ceratonia, Fagus, Fraxinus, Juglans, Pyrus, Quercus, Robinia, Salix, Ulmus*	Bole
Choristoneura murinana	*Abies, Cedrus, Juniperus, Picea, Pinus, Pseudotsuga*	Crown (foliage)
Dendroctonus armandi	*Pinus*	Bole
Dendroctonus micans	*Abies, Larix, Picea, Pinus, Pseudotsuga*	Root, Root Collar, Bole, Crown (branches)
Dendrolimus sibiricus	*Abies, Larix, Picea, Pinus, Tsuga*	Crown (foliage)
Hylastes ater	*Abies, Araucaria, Larix, Picea, Pinus, Pseudotsuga, Thuja*	Root, Bole
Hylesinus varius	*Acer, Ailanthus, Carpinus, Corylus, Fagus, Fraxinus, Juglans, Olea, Pinus, Pyrus, Quercus, Robinia, Syringa, Tilia, Ulmus*	Bole, Crown (branches)
Hylurgus ligniperda	*Pinus*	Root, Root Collar, Bole
Ips hauseri	*Larix, Picea, Pinus*	Root Collar, Bole, Crown (branches)
Ips sexdentatus	*Abies, Larix, Picea, Pinus, Pseudotsuga*	Bole
Ips subelongatus	*Abies, Larix, Picea, Pinus*	Root Collar, Bole, Crown (branches)
Ips typographus	*Abies, Larix, Picea, Pinus*	Bole
Lymantria dispar	*Acer, Alnus, Betula, Crataegus, Fagus, Malus, Populus, Prunus, Quercus, Salix, Tilia*	Crown (foliage)
Lymantria monacha	*Abies, Acer, Betula, Carpinus, Fagus, Fraxinus, Larix, Malus, Picea, Pinus, Prunus, Pseudotsuga, Quercus, Ulmus*	Crown (foliage)
Malacosoma neustria	*Acer, Alnus, Amygdalus, Betula, Carpinus, Castanea, Corylus, Cotoneaster, Crataegus, Fagus, Fraxinus, Juniperus, Larix, Malus, Morus, Populus, Prunus, Pyrus, Quercus, Rosa, Rubus, Salix, Sorbus, Syringa, Tilia, Ulmus*	Crown (foliage)

Insect	Host	Position within tree
Monochamus sartor	*Abies, Larix, Picea, Pinus*	Bole, Crown (branches)
Monochamus urussovi	*Abies, Betula, Larix, Picea, Pinus, Thuja*	Bole, Crown (branches & foliage)
Oberea linearis	*Alnus, Carpinus, Corylus, Juglans, Ostrya, Salix, Ulmus*	Crown (branches & foliage)
Oberea oculata	*Populus, Salix*	Crown (branches & foliage)
Pissodes harcyniae	*Picea*	Bole
Pityogenes chalcographus	*Larix, Picea, Pinus, Pseudotsuga*	Bole, Crown (branches)
Plagionotus arcuatus	*Acer, Carpinus, Castanea, Fagus, Prunus, Quercus, Robinia, Salix, Tilia*	Bole, Crown (branches)
Saperda carcharias	*Betula, Populus, Salix*	Bole, Crown (branches & foliage)
Saperda perforata	*Populus, Salix*	Bole, Crown (branches)
Scolytus intricatus	*Aesculus, Betula, Carpinus, Castanea, Corylus, Fagus, Ostrya, Populus, Quercus, Salix, Sorbus, Ulmus*	Bole, Crown (branches)
Scolytus morawitzi	*Larix*	Bole, Crown (branches)
Scolytus ratzeburgi	*Betula, Ulmus*	Bole, Crown (branches & foliage)
Sirex noctilio	*Abies, Larix, Picea, Pinus, Pseudotsuga*	Bole
Sirex rufiabdominis	*Pinus*	Bole, Crown (branches)
Tetropium castaneum	*Abies, Larix, Picea, Pinus*	Bole
Tetropium fuscum	*Abies, Larix, Picea, Pinus*	Bole
Tetropium gracilicorne	*Abies, Larix, Picea, Pinus*	Bole
Tomicus piniperda	*Abies, Larix, Picea, Pinus, Pseudotsuga*	Bole, Crown (foliage)
Tortrix viridana	*Acer, Betula, Carpinus, Fagus, Populus, Quercus, Urtica, Vaccinium*	Crown (foliage)
Xylotrechus altaicus	*Larix*	Bole
Xylotrechus rufilius	*Acer, Fraxinus, Ulmus*	Bole

GAIP
keeping bees
a complete practical guide
Paul Peacock

More popular than ever, beekeeping is a fascinating craft that is fun to learn and the perfect antidote to the stress of modern life. This practical guide covers everything a new beekeeper needs to know, from buying equipment to harvesting your very own honey.

With clear, step-by-step instructions on handling and checking your bees, helpful tips and advice on keeping them healthy and productive and a collection of tempting recipes for you to try, you'll be sure to catch the honey buzz!

Introduction

If you've picked up this book, you may have been inspired by someone you know who has a hive or two, and you long to produce your own honey. Keeping bees is a most worthwhile pastime; you will make lasting friendships as you learn about bees.

Starting with bees

Of all human activities, the keeping of bees is one of the most satisfying, and it will change your life in ways you could not have imagined. It's a peaceful occupation, the ideal antidote to the fraught pace of modern life, and most beekeepers find that the hours they spend looking after their hives are deeply rewarding.

There are lots of reasons to keep bees, and increasing numbers of people around the world seem to be doing so. Some will be attracted to the products of beekeeping – the honey, wax and propolis, royal jelly and honeycomb – which are so expensive to buy and so useful in the home, medicine cupboard and kitchen.

Other people will be attracted to the social side of beekeeping and join a local group or branch of a national association. There is always something to be talked about – a problem to be debated, a success celebrated or a failure shared. Although it is possible to be a lone beekeeper, it is not advisable, and the large number of associations and clubs that are dedicated to the welfare of bees share an ethos based on the fact that every beekeeper was once nervous and new. In consequence, beekeepers are incredibly friendly and you are certain to receive a warm welcome.

Left: *A WBC hive surrounded by flowering plants providing abundant nectar and pollen to feed the colony.*

Perhaps one of the most surprising reasons for keeping bees is that they are likeable creatures. Few beekeepers ever fully overcome their childhood fears about stings, and it is sensible, of course, to be careful when you are around them, but the way that bees live together and organize themselves is endlessly fascinating, and soon you will find yourself comparing the human world with that of the honeybee.

The calming effect of beekeeping makes it an ideal antidote to the rush and bustle of the modern world, and at the end of the year you will be rewarded with anything from 20 to 100 jars of honey from just a couple of hives.

First steps

It is not possible to learn to keep bees with a book in one hand and a smoker in the other. By far the best way of learning is from someone else who has already had the experiences that you will soon be getting for the first time. The most important first step is to join a local group or association and to watch more experienced beekeepers as they work. You can then refer to a book to reinforce what you have seen.

This book provides a logical introduction to beekeeping, and it will give you the confidence you need to get your own hive or hives. Use it to reflect on what you have learned from other beekeepers and to remind you of what they do before you delve into your own bees. But more than anything, as far as beekeeping is concerned, read for knowledge but learn from your experience.

Are bees for you?

It is difficult to predict how you will react when you open a hive by yourself for the first time. However, there is much that you can do to prepare yourself for that moment, and you may be surprised at how easily a developing interest in bees becomes a lifetime's passion as you become intrigued by beekeeping.

Skills

Although you need no specific skills to keep bees, it is not something that should be undertaken lightly. It requires a serious attitude, attention to detail, a cool head and a willingness to learn.

You should not consider a lack of knowledge a bar to starting to keep bees, and you probably already have all the skills you will need. What cannot be learned, however, and what is perhaps the most important quality in a beekeeper is an ability to relax. An easy, calm manner will be your greatest asset.

The physical requirements – what you actually do in the hives, how you extract honey, feed the bees and check for the queen, and the dozens of other routine tasks – are easily picked up and are certainly no more complex than those required in the kitchen, the garden or your work place. They are all well within the capabilities of anyone who has the time and is ready to learn.

Time

Running two hives will probably take a couple of hours a week, although at key periods of the year, such as swarming time and when you collect the honey, you may spend a little longer. On the whole, however, bees prefer to be left alone. You should also be prepared, especially at first, to spend an evening each week at a local group or club where you will learn the ropes and meet other beekeepers.

Left: *Protected in an all-in-one bee suit, the beekeeper carefully removes frames for inspection, avoiding any sudden movements.*

Right: *A typical brood frame containing a lot of bees and at least two drones.*

Equipment

Most new beekeepers join a society not only to learn how to look after their bees but also to acquire the equipment and clothing they will need before they get their first colony.

The most important items are a bee suit, or at the very least a veil to protect your face, some beekeeping gauntlets or gardening gloves, a hive tool and a smoker. Secondary equipment ranges from some elastic bands, which you can use to keep clothes tucked in and bees out, a bee brush or a feather to remove bees from your bee suit, and a bucket to store the bits of waste from your hive inspections (see also pages 54–7).

Wherever possible it is better to buy new equipment, which will minimize the transmission of diseases, and if you join a national or local organization you will probably be able to get significant discounts on many items. Some of the more expensive and specialized equipment, such as honey extractors, are best shared and kept as a central resource.

As with any pastime, there are plenty of opportunities and incentives to accumulate a lot of equipment, some of which is not necessary, and over the years you will almost certainly pick up plenty of rather strange-looking odds and ends.

Space

A single beehive does not take up a lot of room – a space measuring 1 x 1 metres (3 x 3 feet) will be more than sufficient – and it is possible to have several hives quite close to each other. However, you will need somewhere to put your equipment, and it is sometimes said that for every hive with bees in it you will need one other as back-up. You will also need to keep spares of the elements that go to make up the hive – frames, chambers, supers and so on. A dry, secure garden shed is ideal.

Before you acquire a hive think carefully about its position (see also pages 60–3). Your bees need to be protected from people who might wish to harm them or their hive and should also be kept from accidentally harming your neighbours.

You may want to consider taking out some form of insurance, and your local bee society or association will be able to offer you the best advice.

The honeybee

Getting a worthwhile supply of honey from your hives depends on understanding both the life of individual bees and also how bees live and work together as a colony. It is worth spending a little time on learning about their lifecycle because a single hive will contain 30,000 or more individual bees.

12 The history of beekeeping

Honeybees live in well-ordered colonies made of individuals specially adapted for their role. There is a unity of purpose in the colony, and the whole mass of bees work to well-defined goals: from collecting nectar and pollen, to rearing new members to cope with the increasing workload as the season progresses.

Evolution

Honeybees have been around for over 120 million years, and they evolved alongside flowering plants, having found a niche by obtaining nourishment from pollen and honey, and in return pollinating the plants they visited. All the natural substances that plants use to prevent fungal and bacterial infections also work in the hive as bees incorporate the healing properties of the plants into the honey and wax they produce.

The hive, which is filled with high-energy food that would otherwise naturally spoil because of microbial action, is therefore able to remain practically disease free. And the healing properties of honey, pollen and propolis were so well known and recognized by the ancient Greeks that the scientific name, *Apis*, is derived from the ancient Greek word meaning healer. In ancient medicine, bee's ash (the material left behind when dead bees were burned) was said to have curative properties.

When the queen starts to run out of eggs the colony arranges for her replacement and makes sure that sexual reproduction takes place. The exchange of genetic material that takes place at this time is an important mechanism in the species' fight against disease, allowing any resistance that may have developed in one generation to be passed to the next.

Left: *A wild honeybee colony with folds of honeycomb.*

Early history

Prehistoric cave paintings that pre-date writing show humans taking honey from hives, and over 10,000 years ago both honey and wax were a welcome part of people's diet and lives. The discovery that honeybees retreat from smoke and gorge themselves on honey in preparation to evacuate the colony made a significant difference to early honey collectors, reducing the number of stings and making it easier to take the precious combs. Fire was a fundamental part of human development, and its application to enable people to remove honey from hives eventually became an important tool in bee farming.

The early hives were simple constructions – either a hollowed-out log with clay blocking the ends and with a small entrance on one side or a woven basket covered in clay – and simple log hives are still found in Africa today.

Beekeeping gradually became an important part of agricultural activities, and a land was prized for its ability to produce barley, emmer (wheat), cattle, milk and honey. It is little wonder that the production of valued foods became part of holy and religious rituals and writings. Meanwhile, the relationship between fire, smoke and spirituality came together in a number of ancient religions, including Hebrew, Mesopotamian and eventually Nubian and Egyptian.

The ancient Egyptians regarded beekeeping as part of the religious life of the nation, and priests used sacred smoke to control their hives. More than 6,000 years ago, the Egyptians believed that the sun would drop its tears as honeybees and that they would fall in the human world as honey and wax. The bee became the symbol of the country, and the pharaoh was named the king of bees and master of their spiritual essence.

Honey was expensive in ancient Egypt and was used only by the ruling classes. It was imported from all over North Africa and even from Asia. Honeybees, too, were traded, and the distribution of the local strains across Africa and Asia Minor and even into southern Europe (*Apis lamarckii*, *A. sahariensis* and *A. yementica*) today is a reminder of the ancient honey industry.

Above: *An ancient Greek example of a pottery skep.*

In China, where the first reference to honey was in the *Book of Chinese Medicine* written some 2,200 years ago, beekeeping mirrored the Egyptian methods. In India it has long been a Hindu custom to give a newborn child a taste of honey as a sign of the protection offered by the goddess Parvati.

Greek civilization was also influenced by the honeybee. It is little surprise that honey, called ambrosia, was regarded as the food of the gods on Mount Olympus. Ancient Greek hives – in the form of large, expandable, ceramic-lidded vases – have been excavated, and there are details of how they tended their bees in ancient literature. Hippocrates, the father of medicine, wrote about the culinary and medicinal uses of honey in the 4th century BC, and apiculture developed into a science that was studied as well as being part of secret religious rites.

The way that bees order their lives and the geometry of the honeycombs was incorporated into Greek thought.

Left: *A modern two-basket skep hive. The top basket contains the honey, with a hole separating the brood basket beneath.*

In the 5th century BC the philosopher and mathematician Pythagoras believed that the regular patterns of the honeycomb were a reflection of something that pervaded the whole universe. It was also believed that bees' behaviour, the way they ordered their lives and the way they prepared themselves for winter had parallels in human life, and this was reflected in literature and in the development of democracy itself.

Greek methods of beekeeping – including the development of the lidded hive and the ability to keep colonies on a semi-permanent basis – were passed to the Romans, who subsequently took them around the known world as their empire spread. In the 1st century BC the Roman writer Virgil included a section on beekeeping in the *Georgics*, his writings on rural subjects. Virgil describes the siting and maintenance of an apiary, fighting swarms, the surrounding garden, the nature and qualities of bees, the gathering of honey, diseases of bees and the autogenesis of bees.

After the Roman period, beekeeping did not change much across Europe. Colonies were housed in straw skeps, which have their origins in the Greek pottery vases and are still sometimes used today, especially for catching swarms. Top-bar beehives, in which the bees draw honeycomb on sticks balanced across the top of the hive, are a development of the Greek style, and they have been common in Africa for 2,000 years and are still used by enthusiasts today all over Europe and the United States.

Recent history

The scientific study of bees, particularly the organization of the hive and the bees' industry, intensified in the 18th and 19th centuries. The relationship between the welfare of bees and the welfare of humans was increasingly recognized, and the vulnerability of the hive and the queen – especially through the winter – became topics of study and formed the basis of much allegory.

As communication between beekeepers in various parts of the world improved, discoveries in one country were gradually adopted in others. For example, sectioned hives were built in Russia in the 1820s, and soon after Russian beekeepers found ways of keeping the queen in a particular part of the hive.

One of the most important developments occurred in Philadelphia in the early 1850s, when the Rev. L.L. Langstroth wrote about the 'bee space', which revolutionized beekeeping. If bees are not happy with a space or gap in their living area, they will glue it up. Any space less than 4–5 mm (about ⅛ inch) across will be filled in with propolis (see page 33). If the space is a little larger the workers can get through, but the queen cannot. Rev. Langstroth also found that wax combs were never closer

together than 7–8 mm (¼ inch), and he used these measurements to create a hive in which the queen could be confined to her own brood box while the other bees were allowed the freedom of the hive. Honey can, therefore, be saved in one part of the hive while brood can be developed in another.

The development of a pre-stamped honeycomb foundation in the mid-19th century was slow to catch on, but it eventually combined with the Langstroth hive (see page 44) to create almost exactly the modern beekeeping method. It became possible to harvest honey without brood mixed in with it and to take combs out of the hive without endangering the colony.

Since the modern hive evolved, there have been many changes in apiculture. It has become possible to manipulate a colony to suit the purpose of collecting large amounts of honey. In addition, it has become possible to move bees to take advantage of different crops, from fruits tree to setting honey from oilseed rape fields. A number of different types of hive have developed from the original Langstroth, and it is now possible to have a hive to suit different environments and styles of beekeeping (see pages 44–7).

Despite these innovations, the bees themselves have remained largely the same. They have reacted to threats from disease and adapted themselves to varying conditions all over the world. As a species they are equally at home in a skep, a top-bar hive, a modern hive, a hollowed-out tree trunk or even a dirty old chimney.

Bees have faced many threats in this period. Acarine (Isle of Wight disease) wiped out almost the whole of the British bee population in the early part of the 20th century, and this led to a great upsurge in bee research, which eventually resulted in the development of a strain of bee that was immune to the disease. The parasitic varroa mites (see pages 92–3) are but the latest threat to apiaries, and there are certain to be new ones in future.

Albert Einstein is reported to have said that if the bee disappeared off the surface of the globe man would only have four years of life left, and it is against this background that the lives of humans and bees remain inextricably intertwined.

Understanding bees

Bees have captivated peoples' imagination from the earliest times, and they will continue to do so. The closer we look into their lives the more fascinating they become.

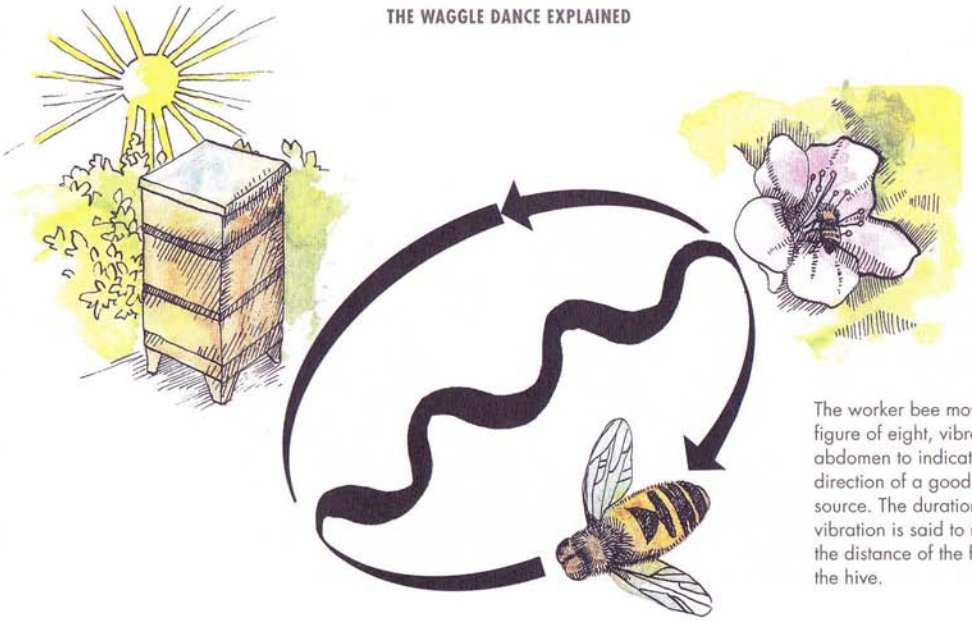
Research and the honeybee

One of the problems facing any researcher into the life of honeybees is that it is all too easy to explain their behaviour in terms of human characteristics. Our preconceptions about them sometimes get in the way of our understanding.

The waggle dance

Some of the most interesting bee research was carried out by Austrian zoologist Karl von Frisch (1886–1982). A well-known entomologist, von Frisch's main work was a study of parasitic wasps, but he also worked on the life of the honeybee, and his ideas about the way bees communicate in the hive evolved into the idea of the 'waggle' dance, which is still debated by entomologists. Not everyone has been convinced by von Frisch's finding, largely because it sounds too human, and it is felt there might be another explanation.

Von Frisch discovered that bees communicate the location of sources of nectar by movements that are called dances, and the 'waggle' dance is a form of communication by which a bee can advertise to others in



The worker bee moves in a figure of eight, vibrating her abdomen to indicate the direction of a good food source. The duration of the vibration is said to represent the distance of the food from the hive.

the hive the location of a promising food source. The bees will waggle from side to side for a short distance, the direction of their waggle indicating the bearing of the food in relation to the sun, and the duration of the waggle indicating its distance from the hive. Von Frisch found that bees are even able to take into account the different position of the sun as the day progresses. When he replaced the sun with a bulb the dance was disrupted and changed, but if even a small amount of blue sky was introduced to the experiment, the bees' dance was orientated correctly, which meant that they could see polarized light and use it for navigation purposes.

Von Frisch's researches also showed that bees cannot distinguish between some shapes but that they can distinguish between some colours, including ultraviolet (which is not visible to humans) but not red. Despite the on-going debate about the waggle dance, von Frisch's observations have become the standard methodology for research into bees.

Above: *Bees place pollen from the same plants together so that it is not mixed with other sources.*

Working together

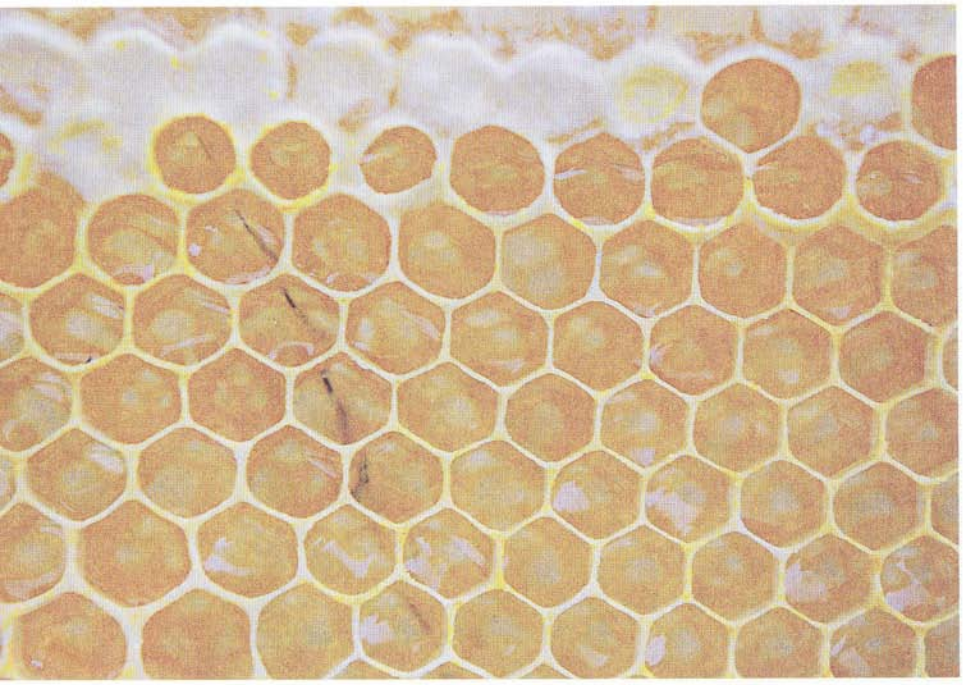
More recent research into the life of colonies has found that bees sort food supplies according to colour and that they are able to differentiate between different food sources and decide, as a colony, which food is to be taken advantage of at any one time. It has also been found that bees can count, that they can elucidate shapes and that they have a wonderful ability to put right what they perceive to be incorrect in the hive. They will secure the defences of the hive and decide together which parts of the hive to work on first.

Overcoming problems

Much research into bee biology focuses on the problems faced by bees around the world. There are almost no feral colonies of honeybees in many parts of the world, and problems such as varroa and colony collapse syndrome remain serious challenges to colony numbers.

Traditional ways of dealing with varroa, for example, are no longer effective because the mites have developed an immunity to the treatments, and new strategies are constantly needed to combat them. Some recent research has been concentrated on the cell size. It is known that varroa mites prefer to inhabit the cells made by workers to house drones. These are slightly bigger than standard ones found in foundation comb, which can be either 4.9 mm or 5.1 mm (about ⅛ inch). It is not known if colonies that make all their own comb – top-bar hives have no foundation comb – have less varroa than more conventional hives.

Sadly, many bee populations around the world are under threat, and research has yet to find the answer. Human activity and interference may be part of the problem, however. Scientists have already interbred bees with questionable results, joining the aggressive traits of the African bee with South American bees to create a race colloquially known as 'killer bees'. Perhaps it is time for humans to start learning from bees rather than merely researching them.



Left: *The cells at the top of this honeycomb have been capped because the honey is ready for storage. Those below are filled with ripening honey.*

Bees and humans

Bees are also the subject of all kinds of modern research in many fields that are not related to their own activities but to their usefulness to humans.

Concorde

One of the most remarkable things about a beehive is the honeycomb structure of hexagonal cells. This has stimulated human imagination over the centuries and influenced research into topics ranging from the molecular structure of benzene to the production of new building materials. The floors of Concorde, the supersonic aircraft, were built like a hive's honeycomb but with a thin skin on either side, and this material proved to be extraordinarily light in relation to its strength. Honeycomb works in much the same way as a modern aircraft's wing. Much of its rigidity and strength comes from the contents being kept full.

Skin

The value of honey in the treatment of skin ulcers is also being researched. Widely used therapies have subjected the sufferer to months, if not years, of agonizing bandages, but the simple application of honey-impregnated bandages has shown promising results, reducing the healing time. The honey used is specially prepared and sterilized, and the boost to the local tissue creates new skin very quickly.

Hay fever

Research into the use of honey to treat hay fever is also giving promising results. The basic premise is that locally sourced honey is charged with pollen and pollen extracts from the patient's home area. This pollen, when ingested with honey, is thought to have the effect of mildly inoculating the immune system, relieving the symptoms of hay fever when pollen appears in spring and summer.

Arthritis

It is commonly said that old beekeepers do not suffer from arthritis, and research is now under way to find evidence about the effect of bee stings. Similar research into stinging nettles and the relief of arthritic pain seems to point in the direction of acetyl choline, a chemical found in bee stings and nettles.

Related research is ongoing into the few people who have a reaction when stung by a bee. This research is mainly linked to the immune system and how it responds to the chemicals in the sting.

Cellular chemistry

Honeybees are also being used for research at the cellular level, and scientists are studying the way honeybee cells respond to invasion, the bee immune system and the role of external bee products, such as propolis, on the internal chemistry of the honeybee. Researchers are learning a lot about the human immune system because of the way that bees fight disease themselves.

There are a number of pressures on bee colonies, particularly as governments begin to realize there is a growing decline in pollinators for agriculture. A lot of research focuses on the combined effects of modern life: pollution, insecticides, GM technology, global warming and on the abilities of bees to fight disease.

Because they have short lives and the colony is of paramount importance, bees put a lot of effort into fighting disease outside their bodies. The colony could be viewed as the organism, and the individual bees as simply a part of it. For instance, during the time nectar takes to ripen to make honey, there is plenty of opportunity for fungi to ferment this liquid. The worker bee mixes enzymes with the nectar to stop this fermentation from happening, the whole colony benefiting from the individual bee's immune system.

Left: *Honeybees are one of the main pollinators for plants and agriculture.*

Classification

The scientific or Latin name of the honeybee is *Apis mellifera* L., and like most botanical names it is largely descriptive. Like other botanical names of plants and animals, it is used around the world so that there can be no confusion from country to country about which particular species is meant.

Left: *Worker bees clean out the cell before the queen will lay a new egg in the bottom.*

Scientific names

The scientific name is simply a description of any living organism, so *Apis mellifera* means 'the honey-bearing bee'. The word *Apis* is the name of the genus to which honeybees belong, and it distinguishes them from other bees – bumblebees, for example, belong to the genus *Bombus*. *Apis* is derived from the Greek word for healer, and the Roman word for the bee was *apis*.

The species name, *mellifera*, means honey bearer, and it describes the honeybee perfectly. It derives from the Latin words *mellis*, meaning honey, and *ferre*, meaning to carry. Honey is called 'mel' or 'mell' in many languages – in French it is *miel* and in Italian *miele* – and we also find it in the word mellifluous.

The L that follows the species name stands for Linnaeus, the name of the person who described the species in the first place. Linnaeus, whose real name was Carl von Linné (1707–78), was a Swedish botanist and the originator of the modern binomial system of nomenclature of plants and animals.

Above: *Look carefully at a group of honeybees and you will see many individual differences.*

Scientific classification

The full scientific classification, or description, of the honeybee is:

CLASSIFICATION	NAME	DESCRIPTION
Kingdom	Animilia	which means they are animals
Phylum	Arthropoda	which means they have jointed legs
Class	Hexapoda or Insects	which means they have six legs
Order	Hymenoptera	which means they have membrane-like wings
Sub-order	Apocrita	which means they possess a sting
Super-family	Apoidea	which means they are bees
Family	Apidae	which describes them as social bees
Genus	*Apis*	Bee
Species	*mellifera*	Honey gatherer

Subspecies and hybrids

The species *Apis mellifera* (honeybee) is divided into about 30 subspecies and many more hybrids. Subspecies will mate with each other and produce viable, hybrid bees, which are generally unique in terms of colour, shape and behaviour.

Among the more important subspecies are *Apis mellifera carnica*, the Carniolan bee originally from Central Europe, which is docile and well suited to cool climates, and *A. mellifera ligustica*, the Italian bee, which is well mannered, rarely swarms and produces lots of honey. *A. mellifera mellifera*, the north European black bee, also known as the British black bee, was devastated by disease early in the 20th century. *A. mellifera scutellata* is the Africanized honeybee, which has a reputation for being more aggressive than the European honeybee, and *A. mellifera capensis* comes from the South African Cape. Within these races are many local sub-races.

The Buckfast bee is a hybrid of many bees from around the world, especially the European black bee and Italian bee, and was developed in Devon, in southern England, by a Benedictine monk, Brother Adam, in response to acarine, the disease that all but wiped out the British black bee.

Genome sequencing

The classification of honeybees around the world has been improved by the Honey Bee Genome Sequencing Consortium, a group of scientists who have worked out the sequence of genes in the DNA of various species.

The comparison of apine DNA has revealed much about the evolution of the honeybee and suggests that other insects have evolved more quickly than honeybees, which appear to have developed in Africa and spread around the world in two waves. Honeybees have fewer genes devoted to the immune system than other insects, a testament to the efficiency of their hive defence systems. The research has also shown that honeybees have over 160 receptors for smell, but only ten for taste.

Anatomy of the honeybee

Honeybees are among the most recognizable of all flying insects, and there can be few people who have not watched them buzzing from flower to flower in a summer garden. Most of the people who could identify a honeybee, however, probably know little about the insect's complex anatomy.

Body

Like all insects, a honeybee has a head, thorax and abdomen and six legs. Bees also have four wings, antennae and large, compound eyes. It is a remarkably successful arrangement, and there are more insects on the planet than any other animal.

The honeybee has no skeleton as such. Instead, it is held together by hard plates covered in wax, a little like a suit of armour. All the muscles are attached to the inside of the plates, and each plate is attached to the next by a tough but flexible membrane. The plates that make up the body are referred to as the exoskeleton, and without their waxy covering the insect would simply dry out and die.

Left: *The head, thorax, abdomen, wings and compound eyes can be clearly seen.*

Bees do not have blood vessels – they do not even have blood, for that matter. A fluid called haemolymph is pumped by a very simple 'heart' around the body cavity, transferring nutrients and oxygen to the tissues.

They do not breathe in the conventional sense and have no lungs. Holes in the exoskeleton, called spiracles, allow air into the centre of the body. When the bee has used up all the oxygen a large muscle rhythmically contracts and expands the abdomen to force air in and out of the spiracles. The spiracles lead to a system of tubes, called trachea, which carry gases to and from the centre of the insect. The trachea are bathed in haemolymph, and the rhythmic beating of the wings or the flexing of the exoskeleton maintains a constant flow of air in and out of the insect. A bee with blocked trachea cannot survive.

The thorax is largely filled with muscles and glands and with the nervous system, which stretches along the length of the lower part of the body. There is no brain as such, but a series of ganglia act as localized processors of inputs from sensors and send motor messages in response.

The gut is divided into many sections. The 'tongue' is a retractable proboscis, which mops up nectar and passes it to the honey stomach via a tube that runs through the thorax. Some partial processing of the nectar

takes place here, and the syrup is ejected at the honeycomb to make stores of honey. Beyond the honey stomach is the rest of the digestive system, a second stomach and the rectum for ejecting waste.

Head

Bees have two large compound eyes, one on each side of the head. Each eye consists of a few thousand simple eyes, each with a single lens. Some of the eye cells recognize colour and others movement. There are also three simple eyes, called ocelli, that recognize sudden shadows that fall over the bee. The first ganglion, sometimes referred to as a 'brain', processes the information from the eyes and creates the 'picture' the bee 'sees', which, remarkably, is not dissimilar to what humans see.

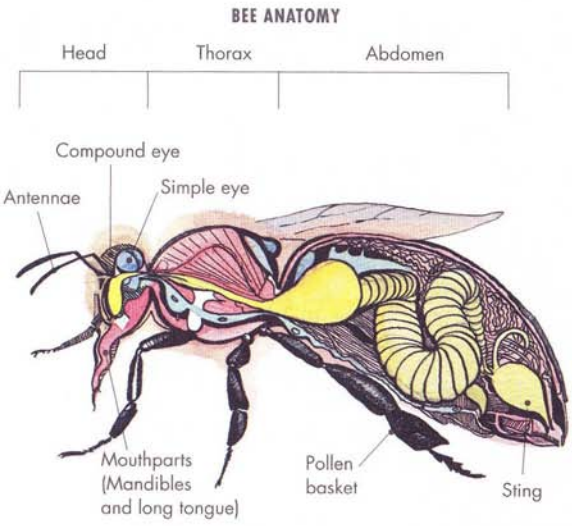
The antennae are packed with chemical receptors, which enable the bee to navigate around its environment. They are particularly important for recognizing the queen's hormones and for detecting any predators that enter the hive.

The mouthparts are adapted for drinking but do not bite. Honeybees also use their mouthparts to construct honeycomb, chewing and placing wax into position and laying down the antiseptic glue, propolis, which they use for structural security and hive health.

Legs

Honeybees have some of the most evolved legs in the entire insect world. The forelegs are similar to those of most other insects in that they are used for the important function of cleaning the antennae and eyes. In addition, the legs have sensory organs, mostly hairs, which enable bees to understand where they are in the world. Organs of balance, which are based on a system of hairs, are not dissimilar to the mammalian inner ear.

The hind legs of worker bees have a pollen basket or sac, the corbicula, in which pollen is taken back to the hive. The pollen is caught on the numerous hairs on the leg and transferred to the basket by the forelegs.



Wings

Bees have four wings, and they differ from the diptera, mostly flies, whose second pair of wings are small or reduced in size, and from beetles, where one set of wings has hardened to create a case. The wings of a bee can beat independently in pairs, and it uses the flexibility of its exoskeleton to help flip the wing back into position, saving on the amount of work of the major muscles. Bees beat their wings billions of times.

The front and hind wing can be hooked together so they can act in unison if necessary. When the bee rests or is not using its wings the back ones fold neatly under the top ones, so it appears to only have two.

Sting

The bee's sting is made up of special reinforced plates with a venom sac attached. Once it has delivered its sting, the bee usually flies away, leaving behind the venom sac and a pair of pulsating muscles, which inject the toxin into the victim. The bee, meanwhile, simply dries out and dies shortly after because its body cavity is open to the air.

Types of honeybee

When you lift a frame from a hive and watch the bees, they seem to be a crowd of busy individuals. However, the whole colony makes up a super-individual, and each bee has a part to play in this 'collective life form'.

Queen

Because the average worker bee dies after about a month, she has to be replaced if the colony is to take advantage of the nectar and pollen the summer provides. The function of the queen, therefore, is to lay the eggs that will be tended by the workers and so build up the numbers of bees in the colony. A fully fertile queen can lay 2,000 eggs a day.

In addition to laying eggs, however, the queen has a number of other functions that are equally important to the colony. Without her special type of hormones, called pheromones, the workers would behave differently, becoming almost aimless and, above all, very angry. The queen's aroma, packed with pheromones, gives the hive its cohesion, and she maintains their loyalty – but only as long as she has eggs to lay. Once her fertility starts to fail the workers notice the change in her aroma and use some eggs to create replacements.

Many people think the queen bee is the ruler of the colony. This is not correct, for she is merely an egg-laying machine. In many ways she is inferior to the workers, and certainly her 'brain' is much smaller. She does not need the complex skills exhibited by worker bees and can usually be easily replaced by the hive. Should she die the workers can start to feed an egg with royal jelly and build up the cell into an emergency queen cell. A queenless colony will produce many replacements, and the first to emerge will often destroy the others. However, if winter comes and the colony remains queenless it will probably die out before spring.

Recognizing the queen

There may be a couple of thousand bees on each frame, and you will have to look carefully to find the queen. She is longer than the workers, a little lighter in colour and has a pronounced abdomen that looks full of eggs. Compared to a worker, the queen's body is tapered and elongated with smaller wings.

Making a queen

The queen is laid into a special cell known as a queen cell, of which there are different types (see pages 79 and 85). She is fed solely on a glandular secretion, royal jelly, which is packed with hormones and honey and makes the young queen grow quickly (see page 31).

Once the queen has emerged she will learn the layout of the hive and be tended by a group of workers, which are about two weeks old. Three days after she has emerged she will be ready to mate, and at this time she flies to around 10 metres (30 feet) into the air and is followed by a number of drones. She will mate with around ten males, whose genitals are pulled away, still pumping sperm into the queen, leaving the males to die.

She will then return to the hive to start her work of laying. Her sisters will have already prepared and cleaned a number of cells ready for her to use.

Worker bees

The workers, who make up the majority of bees in a hive, have different functions according to their age (see pages 28–9). Young bees that have just emerged from

Above: *A marked queen laying eggs on brood frames with workers in attendance.*

the cell wander around the hive, cleaning and removing debris, while other workers police the brood frame.

Worker bees are not able to mate, but they retain their ovaries and produce eggs. If they are allowed to grow they will become drones, but only one in about a thousand drones is actually derived from a worker bee.

Recognizing worker bees

The worker is the smallest bee in the hive. She is shorter than the queen, has a less pronounced abdomen and is often more brightly coloured and strongly marked. Workers tend to have fewer hairs than the queen, but their anatomy is modified for carrying pollen and honey.

Drones

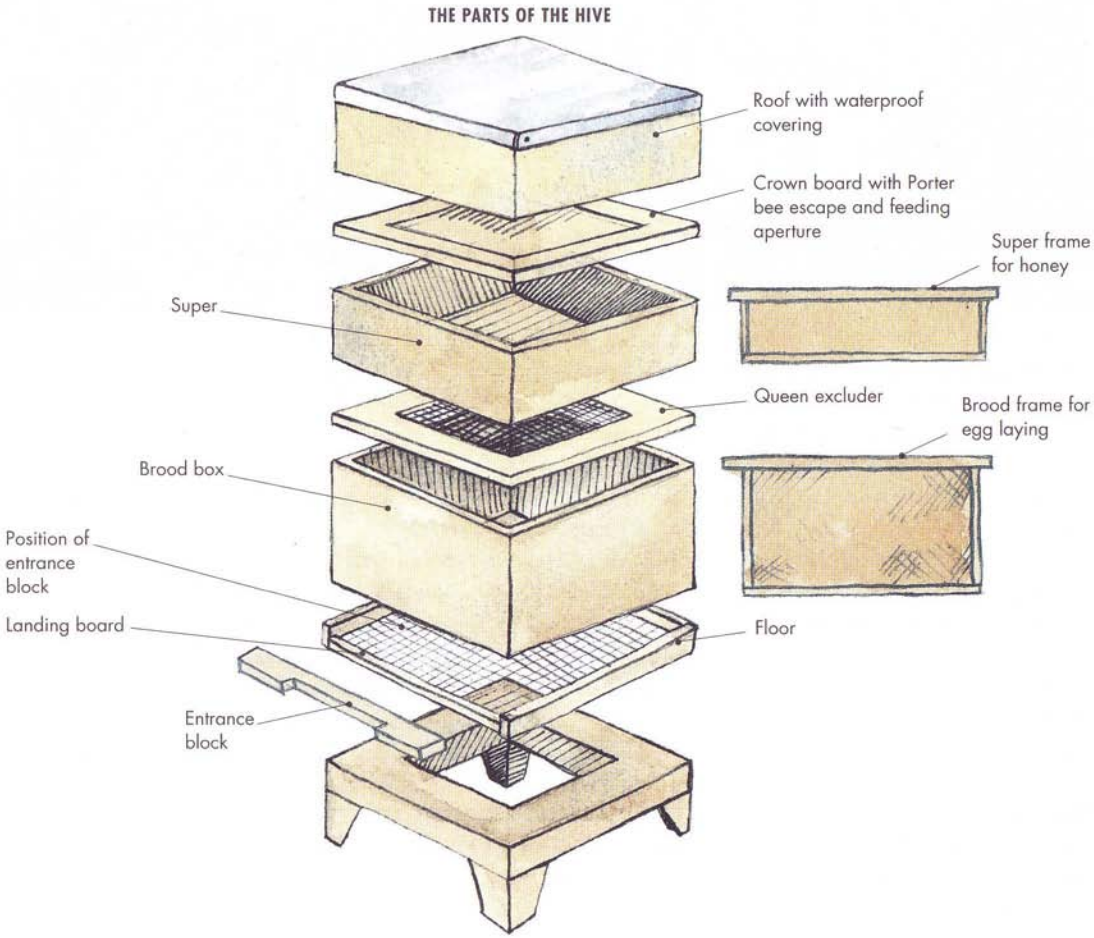
These male bees are squatter and squarer than both the queen and the worker bees, but are nearly equal in size to the queen. There are only ever a few hundred drones in the hive, and their function is to mate with the queen, which only a handful ever manage, after which they die.

Drones start life in a larger cell than worker bees and live for around three weeks. They do nothing around the hive, and at the end of the season they are thrown out, and no matter how much they hang around the hive entrance they do not get back in, eventually dying of hunger and cold.

Drones have no sting and tend to wander around the hive in a seemingly aimless manner, although they might be performing functions we know little about. You are most likely to see drones in the hive in late spring or early summer. Those that remain in autumn are expelled from the hive and left to die.

How the hive works

The colony's lifecycle is governed by the outside temperature and by the length of daylight. Bees are, therefore, more active in spring and summer, when they are seen visiting flowers and flying to and from the hive. Inside the hive the queen starts to lay more eggs and the overwintering workers begin to forage and feed the emerging new workers.



Inside the hive

The queen and the majority of the colony are found in the brood box, which is twice the depth of the honey boxes, also referred to as supers (see below and pages 48–51). She lays eggs in the lower centre of the brood frames and the workers deposit honey in a ring or arch on the outer, uppermost part of the frame. This is called the honey arch.

If you can see developing bees in uncapped (unsealed) cells you can be certain that there is a laying queen in the hive, even if you cannot find her. Once the grub pupates the workers cap the cell with wax. A similar process occurs in cells that are filled with honey: once the honey is ready it is capped to stop it from spoiling.

The queen excluder

A metal grid, wide enough to allow workers through but too narrow for the queen and drones to pass through, is used to keep the queen out of parts of the hive. The beekeeper can decide where to place the queen excluder, but in a new hive it is usual to allow the bees to fill all the brood frames first with brood and honey. The queen excluder is then used to separate this from a single super, where the workers are able to draw out (build) the honeycomb on the wax foundation sheet. Because the queen is excluded from these smaller frames they contain nothing but honey. Once this box is full the queen excluder is placed on the top of the first super, then followed by a second super.

This gives a hive with a brood box and a super of honey for the colony's winter supplies, while the queen excluder separates the hive from a second super, which will be for the beekeeper's use. In most circumstances the colony will need only the first honey-filled super.

Occasionally, when you are opening your hive, you will find that the queen has managed to get through the excluder and into the super, where she has laid eggs. Inspect the excluder carefully in case it is broken. The cause is usually a loose pin at the edge that enables the queen to push up the grill.

The brood box

The size of the colony increases as the season progresses, and all the bees will have to be accommodated at night because bees are one of the few non-mammalian animals to sleep. A full colony will form a 'bolus' or ball of bees in the centre of the brood box, where the hive is warmest, and the extras will spill over into the supers.

During the day house bees will take care of the grubs, they know the whereabouts of the pollen and honey stores and how to make the food they feed to the different castes of bee.

The crown board

Above the supers is a crown board and then a lid. The crown board is used to keep the colony intact under the lid. If you remove the lid of the hive it is difficult to handle the bees inside it – in fact, if the queen happens to be underneath it, it can be almost impossible. Moreover, the lid is difficult to remove if the bees have been able to propolize it (fill in the gaps with propolis; see page 33) because there is nowhere you can easily insert your hive tool to act as a lever. The crown board is easier to lever out if it has been propolized because there is access between this and the topmost super.

The landing board

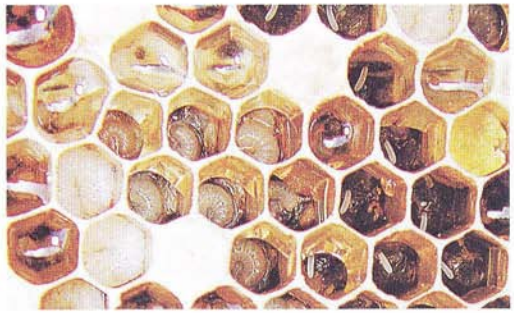
Flying bees find it easier to gain access to the hive if there is a landing (or alighting) board fitted to the base. If there is no board, they fly to and fro at the entrance to the hive and have difficulty getting in, especially if the entrance has been narrowed, to keep the wind out or as an attempt to exclude robbing pests, such as mice.

Feeding

Any feeding should take place at the top of the hive, and it must be done so that the sugar syrup can be added without disturbing the bees too much (see pages 80–3). Although it's a fairly straightforward matter to remove the top of the hive and add some more syrup, do take care to wear your bee suit, even if you are just opening the lid.

The life of a worker bee

Most hives contain about 30,000 bees, the majority of whom are workers. The life of a worker bee covers three periods of 21 days each. It takes 21 days to grow from an egg to a newly emerged bee. Then the bee lives for 21 days in the hive, followed by a further 21 days as a foraging bee.



Left: *Eggs and larvae, known as grubs, in a healthy section of brood honeycomb.*

From egg to bee

Worker bees start life as a fertilized egg, which stands erect in the base of the honeycomb cell. As each egg develops over the next couple of days it falls over on to its side. The egg stage lasts for three days, and because the exoskeleton does not grow with the insect, there is a series of moults as the grub expands. After four moults, some ten days from being laid, the larva spins a cocoon and settles into its cell, which has now been capped. Eleven days later it emerges from the cell an adult.

At this point the now empty cell is cleaned and prepared by the workers for the queen to lay again.

In the hive

For the first couple of days the newly emerged worker finds her way around the hive, cleaning cells, removing debris and generally learning where things are. She locates the honey store and licks the queen, which secretes a chemical on to her that will inhibit the development of her sexual organs. A number of female workers will develop egg-laying capabilities, and these are usually recognized by the workers and destroyed.

Once she has learned where the brood and honey are stored, the young worker starts to feed the larvae, first the older larvae, where she can do least harm, then the younger ones. This period lasts for nine days. She will selectively feed workers, drones and queen larvae on the different regimes each caste requires. The worker bee's royal jelly glands are particularly well developed and peak in production from between six and twelve days after her emergence, and she will use the royal jelly to feed the queen.

In her final week as a house worker, the bee will build honeycomb, cap cells and deposit wax and propolis (bee glue). The cleanliness of the hive is the responsibility of bees at this stage of their development, and they must also maintain the structural integrity of the hive, where they tend to glue everything together with propolis. The worker's wax glands are particularly well developed at this stage. The instructions for creating the hexagonal cells in the comb is in the worker's genes.

Within a week of being a house bee the worker's venom sac will have filled, and she then switches to guarding the entrance of the hive, where she also assumes fanning duties to add to the ventilation of the colony. The airflow sends the queen's aroma into the atmosphere and acts as an attractant to foraging bees.

Outside the hive

At 22 days the worker bee embarks on a life of foraging for nectar, pollen and water. She will also act as a scout bee in case there is a swarm.

Her life as a forager begins with a few orientation flights, which enable her to fix the position of the hive exactly from different positions. There will be a number of these flights over the next few days, and if you move the hive as little as 2 metres (about 6 feet) from its original position, the returning bees will congregate where the colony used to be rather than finding their way back to the hive.

She will gather pollen from as far away as 3 kilometres (almost 2 miles) and travel many hundreds more in the next three weeks, and then, if she isn't lost, eaten, squashed, sprayed with insecticide or killed by a predator or disease, the worn-out worker bee dies after a busy life of less than two months.

Bee facts

- In her lifetime a worker bee will travel about 1,000 kilometres (620 miles)
- The brood box is maintained at a temperature of about 35°C (95°F), regardless of the outside temperature
- It takes 20 kilograms (44 lb) of honey to produce 1 kilogram (2 lb) of beeswax
- If bees are starving they will eat their own brood
- A bee's 'brain' is less than a cubic millimetre, but has a greater number of nerve cells per cubic millimetre than any other animal

Left: *Worker bees clean and feed the young grubs and eggs, then cap the cell when the grub pupates.*

Bee foods

It is the job of the older worker bees to feed the colony, and if you stand near the entrance to the hive you will see the comings and goings of the foraging bees. Natural bee food consists of pollen and nectar, collected from the nectaries of flowering plants. From these ingredients the bees manufacture all their requirements. They also drink water and a source should always be available.

Left: *A worker bee collecting pollen and nectar for the colony.*

Nectar

Nectar is a complex liquid made from a number of sugars manufactured by plants. These sugars are stored inside the foraging bee until she has enough to make it worthwhile to return to the hive.

The complex chemistry that turns nectar into honey begins in the honey stomach of the worker bees. This sugar is regurgitated into the mouths of the house bees, and the process is continued as they mix the solution for up to 30 minutes, adding enzymes and checking on the progress of the honey by taste. Once they feel that the honey is ready they evenly spread the liquid into the cells around the honeycomb so that the water in it can evaporate, thus helping to preserve it.

Nectar consists of about 80 per cent water, but honey is less than 22 per cent, a change that takes place in the honeycomb. Bees speed the evaporation of water by standing on the comb and fanning it with their wings. Once the honey is thick enough the bees put a cap on the cell, which remains in place until the stores are needed.

A colony may use over 50 kilograms (110 lb) of honey during a year, which is quite remarkable when you consider that another 20–30 kilograms (44–66 lb) is often taken by the beekeeper.

Pollen

The tiny specks of dust on the end of a plant's anthers are pollen – the male sex cells of flowering plants. When pollen touches the sap on the female flowering parts it grows until it fuses with an ovum to create a seed.

Pollen is packed full of protein and fat, and it makes an excellent food for young bees. It is usually mixed with water and the small amount of sugar in the bee's mouth, causing the pollen granules to 'grow' to make a substance that resembles bread. The processed pollen,

which is often referred to as beebread, is stored in the honeycomb. Pollen is also used to add structural integrity to the outer parts of the honeycomb.

Bees collect pollen from a wide range of flowers, making at least a million trips in the course of a season. The pollen they collect is said to have beneficial effects for humans (see page 18).

Royal jelly

A rich secretion from the hypopharyngeal glands in the heads of young worker bees, royal jelly (among other substances) is used to feed the larvae in the colony, including workers. The amount of royal jelly fed to grubs depends on their caste: workers receive only a little during the first couple of days of life, drones receive more so that their sexual organs develop, but those grubs destined to become queens are fed on nothing else. Queens themselves are fed royal jelly as well as honey.

A simple analysis of the composition of royal jelly does not reveal its properties. It is mostly water (66 per cent), and protein and carbohydrate in equal quantities make up the bulk of the rest. A small number of minerals have been identified, but there are other substances that have not yet been recognized. It has recently been found that the composition of royal jelly differs throughout the year and that it might possibly have a role in reducing egg laying in autumn and the closure of the hive in preparation for winter.

Minerals and water

Bees need minerals and water in order to thrive. They extract minerals from the plants around them, but a water supply provided by the beekeeper is also important.

Artificial nectar and pollen

Bees frequently need feeding in order to get them through the coldest or leanest parts of the year (see pages 80–3). Feeders can be used to dispense household sugar (sucrose) at a predetermined concentration, and the bees use enzymes to split this disaccharide molecule to create two simple sugars. However, bees that are fed entirely on sucrose can show symptoms of malnutrition. Bees are also sometimes given artificial pollen made from soya flour and other ingredients mixed with honey to make it palatable.

Most beekeepers become good botanists, and you will hear them talking of the lime flow, the apple flow or their equivalents around the world. In temperate climates there is a marked seasonality to the bee's year, depending on which plants are producing nectar and pollen. This is reflected in the fact that in the far north and south, the flows represent an increasing amount of plant activity whereas at the equator bee production is constant, mimicking the long season.

Right: *Local honey is said to be excellent for treating many ailments, including hay fever.*

Honey

This wonderful substance has been valued as the food of the gods from Egyptian times, and it has been a special part of mythology through all civilizations to modern times (see pages 12–15). Beyond honey's historical significance and wonderful flavour, it is magical food.

Honey is packed with carbohydrates, specifically equal proportions of glucose and fructose. These two sugars polarize light in opposite directions, and because bees can differentiate polarized light the honey is ready not only when it tastes right but when it looks right.

Honey also contains a small amount, usually about 2 per cent, of sucrose. The amount of sucrose permitted in honey is regulated and varies from country to country, although it is normally no more than 8 per cent.

Both fructose and dextrose are monosaccharides – that is, they are composed of a single ring of atoms – which makes them easily absorbable directly into the bloodstream and immediately available for metabolic use. Sucrose, on the other hand, is a disaccharide, and needs to be broken down in the gut before it can be used. Glucose is an ideal sugar to take because it can be taken by diabetics and is easily converted directly to glycogen, absorbed directly into the bloodstream.

Honey is acidic in nature, which has led to the belief that it contains some bee venom. This has been disputed by some scientists, but it has also been pointed out that the healing properties of honey cannot derive from the sugar component alone, and many people believe that venom must be present. The curative properties of bee venom have been widely researched, and they are said to help in a number of ailments (see page 19).

Another benefit of honey is that it is an excellent source of antioxidants, and research in the United States has shown that the darker the honey the better its curative qualities. The same research showed that honey was instrumental in slowing the production of LDL cholesterol, the so-called 'bad' cholesterol. Honey is beneficial as a part of a balanced diet, being a sweetener, a condiment and a preserver.

Honey is hygroscopic – that is, it takes water chemically from its surroundings – and for this reason it is frequently used as a preservative as well as a food in its own right.

Honey as bee food

Honey is used by the bees in the hive for all kinds of feeding. Grubs are fed honey, sometimes alone, sometimes mixed with pollen, sometimes with royal jelly. Sometimes the honey has to be diluted, and some water is also stored in the hive by bees for this purpose. Its main purpose, of course, is as a winter food, and the hive will need at least one super full of honey to get the bees safely through until spring.

Propolis

This substance is not actually a product of bees. Propolis is a waxy, resinous substance that is part of several plants' immune systems. Worker bees collect propolis from the plants as they forage, and then when they return to the hive they chew and manipulate it and use it to glue up their hives, filling any spaces that are less than 4–5 mm (about ⅛ inch) wide (see page 14).

Propolis is usually grey-brown to dark brown, and it can be found in any crack or scratch in the hive. When you pull frames out of the box you will find that they are often hard to move because they have been 'glued' in position by propolis, which eventually sets to become very hard. Propolis is quite brittle and cracks easily.

Because propolis originates in the leaf buds of a range of plants, from *Aesculus hippocastanum* (horse chestnut) to *Populus* (poplar) and various firs, it varies in content throughout the year as the plants from which it is gathered come in and out of season. Sometimes propolis is mixed with a little pollen, but it is always rich in aromatic compounds, from which it derives its useful antiseptic characteristics.

Within the hive propolis is used for its antibacterial properties, and it is known to reduce disease and parasitic activity in the hive. It is also used to improve soundproofing and reduce vibration, and any intruder that the bees are unable to drag out of the hive, such as a large insect, slugs and snails or even a mouse, will be completely covered with propolis.

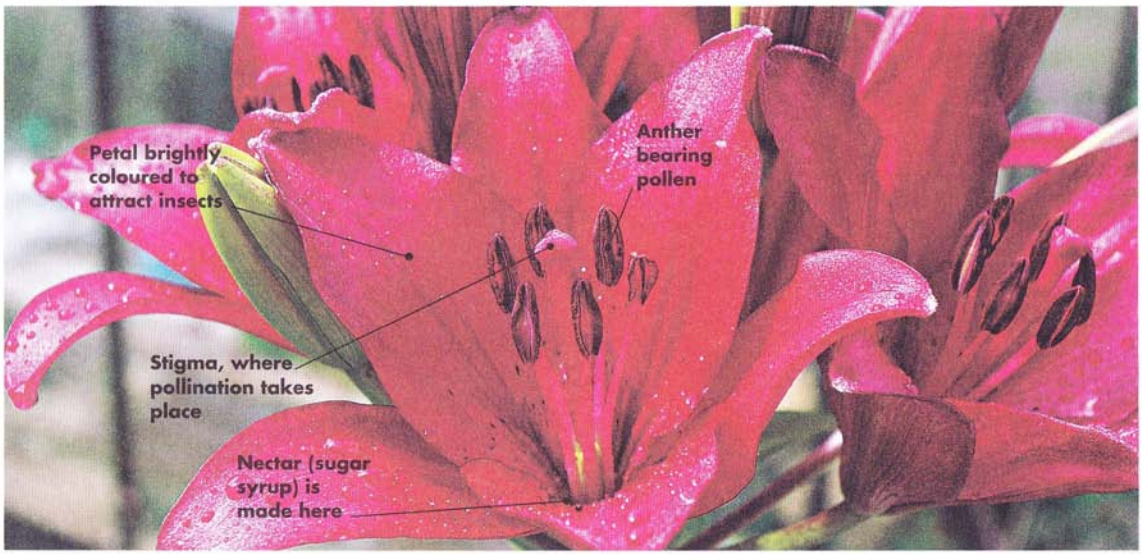
Above: *During the summer months bees work hard to collect all they need to get through the winter.*

It used to be said that bees used propolis to seal the hive against the elements, but modern research has shown that a colony will do well with increased ventilation in winter. Researchers are concluding that propolis is not used as a weatherproofing material.

Humans have used propolis extensively in holistic medicine for many years. It is said to be a remedy for sore throats, and some beekeepers believe that putting a piece of propolis in the mouth will help keep bacteria and viruses away. It is also said to be useful in the treatment of skin ulcers, inflammations, burns and scalds (see page 103).

Pollination

Honeybees are the major pollinators of crops all around the world. Their efforts increase agricultural yields by as much as 30 per cent and in areas where there is a shortage of honeybees, agriculture invariably suffers as a result.



Bees and plants

Bees are uniquely important as pollinators because they evolved in symbiosis with flowering plants. Although there are other pollinators – flies, moths, beetles and, of course, people themselves – and although some plants are wind pollinated, the majority of important crops are pollinated by bees.

When they are foraging bees actually work a crop, and the pollination is not a secondary consequence of pollen collection. The evidence for this can be seen in the higher percentage of pollination achieved by bees on crops compared with similar numbers of other insects. A beehive on an allotment, for example, will increase the crop yield by more than 30 per cent, and this is seen no matter what crop the bees are working on. Traditionally, bees have been used to 'top-dress' fruit trees in spring, then have moved on to fields of oilseed rape in early summer, then on to flax, lavender, lupins, alfalfa and so on through the seasons.

Farmers pay a premium for the services of bees, and this fee is much more valuable than the amount of honey that is gained from the field. Commercial beekeepers combine these activities with rearing queens and producing the nucleus of new colonies. There have been

several estimates of the value of pollination. In the USA it was estimated at $9.3 billion in 1987 and $14.6 billion in 2000. This takes into consideration the increase in crop yields should an alternative pollinator be necessary.

Around the world there are a number of areas where there are not enough pollinators available for crops, and the problem has become severe enough for the Food and Agricultural Organization of the United Nations to set up the International Pollinators Initiative (IPI). The problem is particularly severe in parts of China, Nepal and India, where the use of pesticides has made beekeeping increasingly difficult. Beekeepers have, naturally, tried to keep their bees away from areas where they know that crops are likely to treated with pesticides, but the result is that when the crops need pollinating there are no bees in that area to do the job.

How pollination works

Pollen is the male sex cell of flowering plants. It consists of fat and protein, but no sugar. As soon as pollen comes into contact with sugar it starts to develop a long tubule that has DNA at the far end. This DNA is designed to fuse with the DNA in the egg that is protected deep within the carpals of the fruiting body. Once this occurs the fruit will develop as it should.

Normally, pollen is produced well away from the female parts of the plant, and as bees crash around the flowers in search of nectar and pollen a high percentage of male sex cells from other plants of the same species will hit the sticky, sweet stigma, the foremost tip of the female parts of the flower.

Most flowers are arranged in whorls: first the sepals and petals, then the male sex organs (known as the androecium or male house). The inner whorl, which is often fused to make a single unit, is the female sex organ (called the gynaecium or female house).

It is impossible to guarantee which pollen goes to what plant, but it is statistically evident that enough pollen of the right type falls on to the plant's stigma for successful pollination to occur.

Right: *A honeybee searching for nectar and pollen.*

36 Avoiding stings

Humans have been hard-wired to panic when they see an orange and black insect coming towards them. Indeed, this tendency for alarm has been so embedded into millions of years of evolution that some insects with no stinging mechanism replicate bee markings in the hope that we and other animals will leave them alone.

Trust your kit

Bee suits are designed to stop bees from stinging, particularly if you wear a good layer underneath (see page 54). The net visor will keep bees out of your eyes and away from your face, and if you are afraid – quite reasonably – of bees stinging your head and neck through the cotton suit, wear a hat.

The only possible exposed part might be your hands, but you can even cover these with garden gloves or beekeeper's gauntlets. Even though you might have seen some beekeepers dealing with their bees with bare hands, it doesn't mean that you will be a better or poorer beekeeper if you follow suit. Don't be unnecessarily macho, no one likes being stung.

Once you are covered you can begin to relax and to enjoy the relationship between you and your bees.

Using a smoker

The most important piece of equipment you have is your smoker, which, used correctly, will cause the bees to recoil and fill up on honey. Their extended stomachs make it less likely that they will sting. Using a smoker is described on pages 73–4, but a small puff at the entrance will warn the bees that you will be entering the

Left: *A smoker with its fuel: old pine cones, dried rotted wood, and grass.*

Right: *Working in the hive is comfortable when you trust your kit and have a routine.*

hive. Remove the lid and give another gentle puff. The aim is to waft the smoke over the bees in a single motion.

Smells

Bees do not like unusual smells and will attack anything that has a strong smell. Beer or garlic on your breath, perfume and cologne, sweat, hairspray – all of these can make bees skittish, and even though they will not all fly towards you in a frenzy, you will notice more of them flying into your visor and there will be more buzzing around your head.

Left: *If you stand in the way of bees at the entrance, expect to be covered within a short time.*

Jewellery

Bees often fly straight towards anything that shines, and if you are going to work with bare hands you might want to remove any rings you're wearing and your watch. Bumps and folds in clothing, often caused by watches or bracelets, can become places where bees congregate, and if they get trapped they can attempt to sting.

The hive

Do not stand in front of the hive entrance, where the bees fly in and out, because when you have finished you will find that your back is covered with foraging bees that have returned and landed on you. It is not unusual to see a couple of hundred bees on the back of an unwary beekeeper's suit.

Don't panic

If you are a newcomer to beekeeping it is a good idea to enter a hive for the first time with an experienced beekeeper, which will at least give you the experience to realize that there is no need for panic around a large number of bees.

Even if you do get stung, which is likely at some point, keep calm. It's best to remove the sting with the flat of your hive tool. Don't squeeze the bee because you will only force more venom into the wound. The venom is packed with histamines, and the sting will feel a little like a mild burn. Although it is an unpleasant sensation, it is not unbearable.

Some people say they will allow the stinging bee to twist itself off the skin, stopping the sting from becoming dislodged and killing the bee. This excessive attention to the bee is not necessary: get the bee and its sting off you as calmly and as quickly as you can.

Some people react badly to stings. An antihistamine tablet often helps, but if you feel short of breath or dizzy,

Above: *A bee sting still pumping venom is best removed with the edge of a hive tool.*

Dealing with a sting

If you are stung, do not squeeze the bee, which will only force more venom into you. Slide it away with a finger nail or your hive tool. Take an antihistamine tablet if necessary and if you get any symptoms, such as shortness of breath or dizziness, seek immediate medical advice. Some people recommend putting honey on stings, but for most people the pain will last for maybe five minutes and then pass.

especially after the sting has stopped hurting, seek immediate medical advice.

Why do bees sting?

Drones have no stings, and although queens have stings, they use them only to kill other queens, and they have hardly ever been found to sting anything else.

Worker bees do sting. The sting has a barb on the end, and so each bee can sting only once unless you are prepared to allow her to writhe on your skin to set herself free. A worker bee only ever uses her sting to protect the colony, never herself, because delivering the sting usually ends in her having half her abdomen ripped away as she is swatted away.

Bees sting mostly when they are at or near the hive, and it is actually a reflex action, which the bee performs when it feels threatened. The idea that what is bad for the individual bee is bad for the colony controls the bee's reaction. If you kill a bee at the hive it will release a pheromone that will make the other bees more likely to sting. The same pheromone is produced by bees that see you waving your arms around, that smell your perfume or sweat, that hear you making loud noises around the hive or that see you wearing dark clothes. You will notice the bees fanning pheromones to alert more and more bees, and if you shake down bees from a frame a sudden burst of activity will take place.

Bees will warn you before they start stinging. They will fly at your face and whizz around your head. A high-pitched vibrating in your ears is a warning that you are considered to be an invader.

'Killer bees'

In parts of North and South America Africanized honeybees are regarded as a problem because what seems like the whole colony will attack. They are similar to the European honeybee in that each bee will sting only once, and they are not possessed of powerful venom. They will warn you in the same way as European honeybees, and if you are not wearing a bee suit the best thing to do is run away. The bees will follow you for up to 200 metres (about 220 yards), but you should, just about, be able to run more quickly than they can fly.

Cover your face if you can and do not go into water, because the bees will simply wait around for you to come up for air.

It is unlikely these bees will survive in Europe if they are ever introduced because they cannot survive cold winters, but climate change makes their future spread uncertain as temperate region winters become warmer.

The hive

In the wild bees build nests in inaccessible places – the highest branches of trees or on overhanging rocks – but the beekeeper's aim is to provide his honeybees with somewhere they can live, visit plants and produce honey, so that the beekeeper can then conveniently remove the honey without disturbing the bees. To this end, humans have developed various styles of hive.

The hive

The hive is not just a place where bees are kept, it is a way of controlling, feeding and harvesting and good beekeeping involves becoming proficient in using it.

What do you need from a hive?

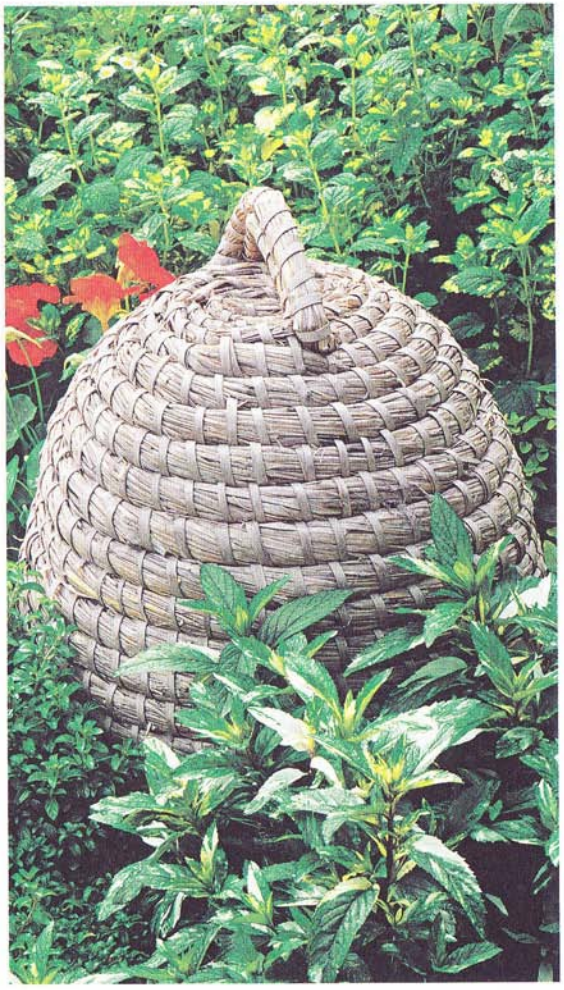
When you are purchasing your first hive there are a number of factors to take into consideration. Importantly bees come first. If they are not happy or healthy in the hive then there is no point in keeping it. Secondly, the hive must be easy to work with. This means it has to be light enough to lift around yet strong enough to take the weight of all that honey – which is much heavier than water. A super will weigh around 12–15 kilograms (26–34 lb) and you need to be able to lift this without damaging yourself.

Most hives are anchored with a restraining strap these days, unless they are in a very sheltered position, which enables hives to be made from lighter materials. PVC hives have excellent insulation properties and you get more brood for your money with them, but without strapping they are likely to blow away in a high wind.

You should consider how many pieces the hive breaks down into. When you are piling up supers inside outer covers, and having to deal with the bees at the same time it is easy to get confused about how to reassemble it.

Standardization

Beekeeping has been made easier by having equipment and accessories of the same size and specification. For this reason it is best to use similar equipment to other beekeepers in your district or club. This way you will be



Right: *A single compartment large skep hive, in use today as it has been for many hundreds of years.*

Above: *A row of modern hives in an apiary. Notice how the heights indicate the size of each colony: some with many honey-filled supers, others with one.*

able to get a ready supply of boxes and feeders, queen excluders, floors, lids, foundation, frames and crown boards. In the UK the National hive is most common. In America and many parts of the world the Langstroth or the Commercial hives are most popular. However, in most countries a large number of hive types are available. See pages 44–7 for further information.

Types of hive

There are several types and sizes of hive, and your choice will largely depend on what is available and what is used in your area (see pages 64–5). They range from simple skeps, which can be used to capture swarms, to more complicated arrangements with several supers.

The main problems with many types of hive are that it is not possible to inspect individual sets of brood, it is difficult to locate the queen and the honeycomb is mostly a mix of brood and honey. The ability to take out individual frames of honeycomb is one of the features of the modern hive, and it was developed not, as many believe by the Rev. Langstroth, but by a Russian beekeeper, Petro Prokopovych, who also invented a simple wooden queen excluder, made of wood and with holes drilled in it. Modern hives are all designed around the minimum bee space, 4–5 mm (about ⅛ inch), which is the room needed for a worker to move comfortably around the hive. Bees will use propolis to glue up gaps smaller than the bee space.

Skep

This traditional hive is basically a large straw or wicker hat-shaped container with a hole in it for the bees to get in and out. A skep has no base, and the bees hang from the 'roof', from which they draw (build) their honeycomb. The bottom of the skep is completely open, but the bees do not seem to be troubled by the extra ventilation in the winter. Even if you have a skep you are unlikely to use it in the long term, although it can be useful in an emergency for capturing a swarm. There are many designs of skep, depending on the requirements or location. Skeps are remarkably warm in winter and are exceptionally good for harvesting propolis.

Top-bar hive

The bees' ability to draw their own honeycomb from a stick or any overhang has long been used to the advantage of beekeepers. Top-bar hives provide nothing more than a bar from which bees draw down their own honeycomb. They are, in fact, only a little more complex than a straw skep, and you get honey as it used to be before modern hives were developed. There is no physical way of separating the brood from the honey stores, but by moving bars around it is possible to keep the brood nest at one end of the hive and the stores at the other.

You cannot spin the honey out of the honeycomb using an extractor. Instead, it has to be allowed to drip into a bucket or is pressed and filtered. Many people eat the honeycomb and honey together.

Langstroth hive

The Rev. Langstroth collated information on the distance between frames, the bee space (see page 14) and optimum hive dimensions, and he came up with a style of hive that is now used almost everywhere in the USA. It has a deep brood box that contains ten frames and shallower supers.

Right: *Two beehives with double brood boxes from a commercial apiary.*

Right: *The WBC hive can still be bought but are not used as much in recent years because of the cumbersome nature of the outer boards.*

National hive

The National hive is the one most often used in Britain and Europe. It is similar to the Langstroth in that it consists of separate boxes for the brood and honey. The opening of the hive allows the frames to be stacked either parallel to the opening or at 90 degrees, which alters the path of air: parallel frames are known as the 'warm way'; angled frames are known as the 'cold way'.

The frames are flush with the top surface of the box, and the bottom surface is deeper than the end of the frames, creating a bottom bee space. The bees are able to crawl over the top bars of the frames because of the space afforded by the frames above.

WBC hive

The William Braughton Carr (WBC) hive is what most people think of when they imagine a hive. It has pagoda-type frames that create an outer wall for insulation. The WBC takes the same frames as the National hive, but it fits only ten frames. It is less common than other hives, partly because it is more expensive and partly because it is inconvenient to have to dismantle the outer covers. When moving the WBC hive, the outer boards take up a lot more space than a National or Commercial hive. A number of variations of the WBC hive exist that are especially designed to help bees cope with consistently poor weather conditions or strong winds.

Dadant hive

This type of hive is fairly similar to the Langstroth, and you sometimes hear beekeepers talk about Dadant–Langstroth hives. It has ten frames and is largely similar to the Langstroth in that almost all the parts are interchangeable. The largest of the hives, the Dadant is found in France and some parts of Spain, but is not used in many other parts of the world.

Smith hive

This hive holds 13 frames that are of the same dimensions as those used in the National hive. It is a top bee space hive, which means that the frames come flush with the base of the box (see page 46), and there is a gap at the top for the bees to move around the frames. It is little used by newcomers to beekeeping today, but the extra frame makes it a popular style of hive with those who do still have one.

Commercial hive

This type of hive has the same dimensions as the National. It is available as either top bee space or bottom bee space and is often used with brood boxes above the queen excluder. The size of this hive is used to create a strong colony, which will produce a large volume of honey in the supers. The supers of Commercial hives are frequently just brood boxes on top of the queen excluder, allowing the colony to produce up to 23–27 kilograms (50–60 lb) of honey per box. Commercial beekeeping is a heavy job during harvest! It is not uncommon to see a Commercial brood box with National supers because of their lighter weight.

Right: *The lid of a National hive being removed to show the crown board beneath, with notes attached to the board.*

48 Parts of a hive

The modern hive has evolved over many years and will continue to change in response to the challenges that new pests and the requirements that a developing honey industry brings. What is now considered best practice is very different to the rules followed a decade ago, and the same will apply, after another decade.

Above: *The mesh of a varroa floor ensures that mites that fall from the bees actually exit the hive completely.*

Stand

This has many functions in addition to raising the brood box off the floor. By the time your honey supers are full they will be quite heavy, and making sure that the top brood box is at a suitable height will make lifting them as convenient and comfortable as possible.

Floor

Many beekeepers still use solid wooden floors of the correct dimensions for their particular hives. However, research into the ecology of the hive has shown that varroa mites that fall on a solid floor can climb back into the hive and reinfect your bees. An open mesh floor allows the mites to fall out of the hive, and bees seem to thrive with the increased ventilation.

The floor also provides an alighting point for bees to land on when they are returning to the hive.

Brood box

The brood box is the chamber where the mass of bees congregate around the queen and where she lays her eggs. She will lay where she feels the temperature is right, and this tends to produce a large semicircle in the bottom half of the brood frames. There are usually 10, 11, 12 or 13 frames in the brood box (depending on your type of hive), and the brood nest is usually centred on the middle frames, but then spreads out to fill the whole chamber.

Queen excluder

This is an ancient invention (see page 27). Pieces of wood with holes the size of a worker bee drilled in them have been used in the earliest of the modern hives to keep the queen in a particular section of the hive. Because the queen is fatter than the workers, she is unable to squeeze through the holes.

Modern queen excluders usually take the form of a metal grill, and they fit on the top of the brood box.

Top bee space or bottom bee space?

Your hive will be either a top bee space (with a space above the frames) or a bottom bee space type (with a space below the frames), and you will notice that there is a space underneath the grill of the excluder. You must remember to position the grill so that bee space is maintained for your particular style of hive.

The bee space varies in size according to the bees themselves. In order to understand the bee space you should visualize what is going on in the hive. Bees on adjacent frames need to be able to work back to back in order to get inside cells.

Clearly the drone and queen are much bigger than the worker and this is reflected in the design of the queen excluder, which has a space that is large enough for the worker, but too tight for the queen. The gap on the excluder is 4.3 mm (about ⅛ inch), but a damaged one might have a 'hole' in it – a bent bar allowing a space enough for the queen to squeeze through.

The space also has a bearing on the way bees protect the hive. During the winter, bees will often narrow the gap around the nest site to as little as 7 mm (¼ inch) so individual bees can crawl through but predators find it more difficult to enter the hive.

Of course, in the case of the top-bar hive and skep, the concept of the bee space means nothing to the beekeeper – but the bees themselves will create comb that conforms roughly to bee space principles for security and weather protection.

Petroleum jelly

Bees tend to use propolis to glue up everything within the hive, and separating surfaces can be awkward. If you cover abutting surfaces with petroleum jelly or a solution of liquid paraffin and beeswax, the bees will not glue these surfaces, making them easy to separate and work with.

Above: *A new brood box with clean frames, all ready for the introduction of a new colony.*

Above: *A smart super filled with new honey frames early in the season for the young colony to make wax cells for honey storage.*

Supers

The supers are usually half the depth of the brood box and consequently have only half-sized frames in them. They are normally reserved for honey stores, and a queen excluder is usually placed between the brood box and the super so that no eggs will be laid in the honey frames, assuming the queen excluder is not damaged.

A mature colony in the height of the season might have several supers of honey – not all of which are destined for the colony.

Crown board

This is a board that covers the whole of the top of the highest super, and it is simply a device to keep the bees at bay when you have removed the lid of the hive. There are usually a couple of holes cut into the board through which you can feed the bees by means of a feeder, or you can place a Porter bee escape into the hole. This is a device that acts like a one-way valve, allowing bees out of the hive, but not in again, and forcing them to re-enter through the bottom.

If you have no queen excluder you must check under the crown board for the presence of the queen when you lift it from the hive.

Some modern crown boards do not have holes in them, and they are simply a covering. (It is an excellent place for keeping your notes on the colony.) You can get crown boards with a bee space on either side; otherwise, you will have to position the board to preserve the bee space.

Lid

The lid of the hive, which must be waterproof, usually has a metal covering. Some lids have ventilation and escape holes, others do not. The lid overhangs the top super, and these two together form a locked unit. Some beekeepers paint identifying shapes on the lid.

Strap

If your stand is fixed to the ground secure a strap around all the boxes and over the lid of the hive, passing it through the stand, so that it will keep the entire hive secure in gusting winds and also from vandals, who have been known to turn over hives. A strap is really important if you are using a polystyrene hive, which is particularly light and susceptible to strong winds. The nylon strap with metal locking device has revolutionized beekeeping. It is completely secure and strong enough to anchor the whole hive to the stand – assuming the stand is in turn anchored to the ground. One drawback is that the cheaper ones can have clutches that corrode, making it a bit of a problem opening a hive after a long absence after the winter.

Caring for a wooden hive

Wooden hives should be scorched before use with a blowtorch to kill any pests or diseases that lurk in the grain and corners, and the wood should be intact, without any cracks or warps.

As with most aspects of beekeeping there is some debate about painting hives: some beekeepers say bare wood is best, because this allows condensation inside the hive to evaporate naturally. Others say that the paint causes the wood to swell and eventually dislodges nails and joints. Many beekeepers, however, paint their hives inside and out, or at least treat the wood with preservative. It is a good idea to paint the hive in colours that do not stand out too much, particularly if it is in an urban area. Exterior-quality paint is adequate, as is wood preserver, but you must make sure that the hive box is very well ventilated and thoroughly dried before you introduce the colony.

Above: *Fixing a hive with a strap. Notice the box below the floor and brood box. This is simply to raise the hive to a comfortable height.*

Frames

Movable frame hives, a little like modern top-bar hives, have been around since at least the late 16th century. They made it possible to remove individual combs for inspection. Better still, most of the bees remained undisturbed. Modern frames are designed to be easily and quickly removed.

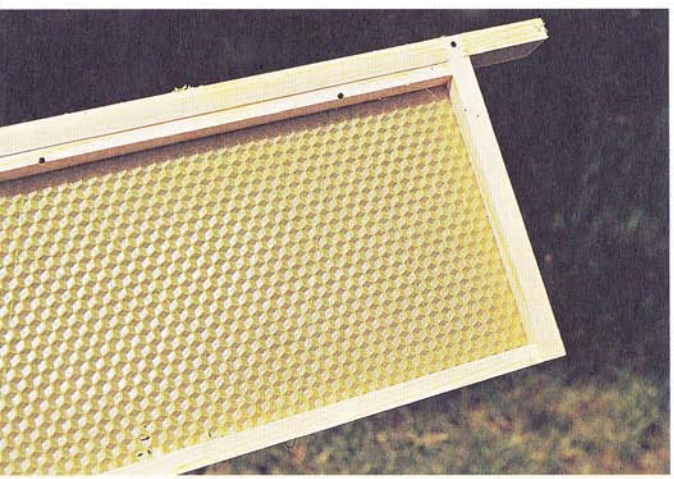
Modern frames

Modern frames are quite complex in design yet simple in construction, and you will need to buy frames that will fit into your hive. British National frames fit National, Smith and WBC hives, or you can buy Langstroth, Dadant and Commercial frames.

Frames are available in two sizes – one for brood boxes and the other for supers – and they hold a template for workers to build the comb. The template, called foundation, is stamped beeswax – bees will not make up on any other substance, such as plastic. Foundation was invented in 1857 by Johannes Mehring, and it took several years to take off but has now become standard. It is mostly bought as worker-sized cells, but you can also get the larger, drone-sized foundation.

The foundation has a wire running through it, and there are two types. In one the wire forms an M, and in the other the wires are laid singly, appearing at the top of the sheet. In the M-style foundation, which is common in Britain, the sheet goes into the frame so that wires create an upright M. The single-wired sheets are more usual in the USA.

Like everything else in the modern hive, the frames are designed to preserve the bee space.



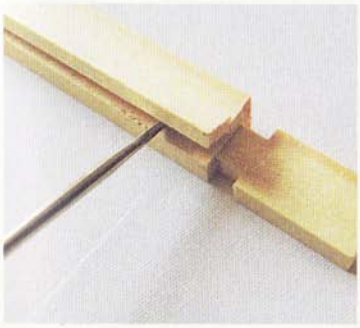
Assembly

A frame has several parts and it has to be assembled before it can be used in the hive. Although the size and style of frames vary from hive to hive, the basic principles remain the same for each. A wired, pre-pressed wax sheet with a template for the cells is sandwiched between pieces of wood that maintain the bee space within the hive and allow the frame to be easily removed for inspection.

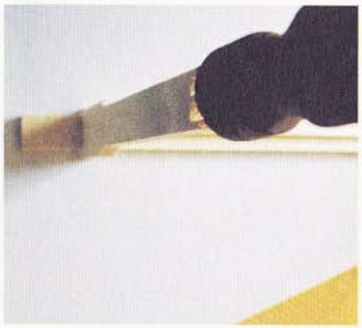
Left: *A super frame with pins holding it together at the most strategic points.*

How to assemble a frame

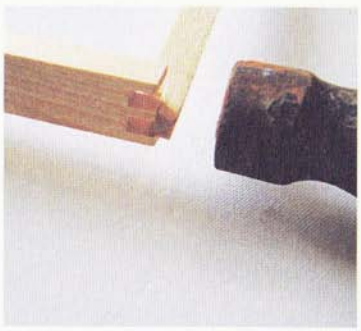
A frame has several parts and it has to be assembled before it can be used in the hive. Although the size and style of frames vary from hive to hive, the basic principles remain the same for each.



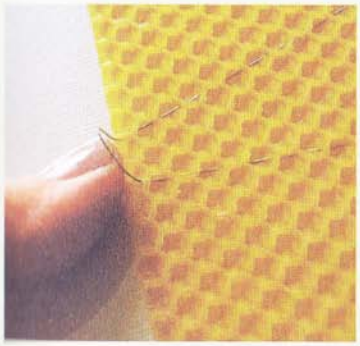
1 Use a penknife or similar to prise out the loosely attached strip of wood in the top bar (it will eventually be nailed back into position). Take care that you do not split the wood.



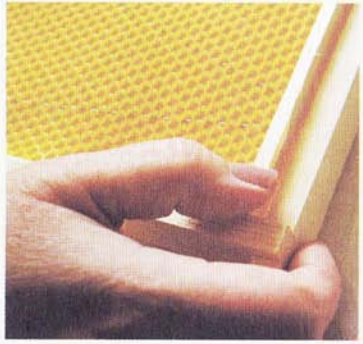
2 Hammer a couple of 19 mm (¾ inch) gimp pins to hold the bars in position. The top bars and sidebars will fit snugly together with the cut-out slits to the inside.



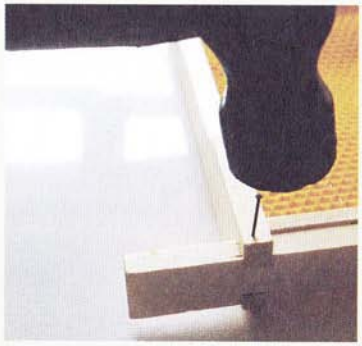
3 Assemble one pair of the bottom bars to create a recess in which the foundation will sit.



4 Take the wire that comes out of the bottom of the sheet of foundation and cross it back over the surface of the sheet.



5 Pin back the trapping bar into position and assemble the other bottom bar to make a perfect frame.



6 Pin all the joints and make sure the whole assembly is firmly joined together.

The beekeeper's toolkit

Beekeepers need a wide range of tools, equipment and special clothing to protect themselves from bee stings. You can purchase this equipment through your local beekeepers' club.

Bee suit

An all-over bee suit is one of the most important items you will need. Not only will the suit stop bees congregating in the folds of clothing or up your trouser legs, but it will add an extra layer of fabric so that bee stings are not able to penetrate to your skin if you have reasonably thick clothing under it. The built-in veil will stop bees attacking your face and vanishing down your ears, which is a thoroughly unpleasant experience.

You should launder your bee suit as often as possible so that infections are not passed from hive to hive, or even from apiary to apiary.

If you wear gauntlets make sure that the sleeves of the bee suit are on the outside to avoid any creases in which bees can congregate. Gauntlets do not afford complete protection, and in any case you really do need to be able to feel with your fingers as you inspect the hive. For this reason many beekeepers prefer to wear latex gloves, changing them regularly to maintain good hygiene around their hives.

Boots

It is a good idea to wear sturdy boots that will give you a good purchase on the ground. It is vital that you do not slip or fall over when you have a frame of bees in your hands. Make sure that your bee suit forms a seal over the boots so that bees cannot congregate around the tops of your boots and find their way into your socks.

Right: *A well-clad beekeeper in bee suit and veil, Wellington boots and gloves.*

Above: *A well-stoked smoker producing lots of cool smoke.*

Smoker

A good-quality smoker is likely to be the most expensive piece of equipment you will buy. You can burn a range of materials in the smoker, from wood shavings and paper to dried pine cones and grass clippings, but make sure that you take care of the bellows and do not allow them to get too wet, when they sometimes rot.

There are several styles of smoker, but they all operate on the same principles: you fill the chamber with paper and a material, such as old wood, and once it is properly alight you close the lid. Avoid over-vigorous pumping with the bellows or you will end up with flames coming from the funnel. You are aiming to deliver a cloud of non-acrid, cool smoke.

Above: *Smoker fuel can be anything from old wood to pine cones or grass.*

Above: *The hive tool with a sharp hooked edge. The hole is excellent for removing bee stings.*

Above: *The hive tool is a wonderfully designed piece of equipment. Here, it is levering a heavily glued-in frame.*

Hive tool

This small tool is a design masterpiece. There are two types, one with a J-shaped end and the other a scraper with a curved end. Some beekeepers like to have both types, but one or the other is usually sufficient, at least at first. You can use the tool to scrape away comb and queen cells from the side and bottom of frames, to separate and lift frames that have been glued together with propolis, to clean hives, to inspect cells, to hold bees and to destroy queen cells. As you gain experience with your hive you will continue to find new uses for it.

Bee brush

A bee brush is mostly used for removing bees from your bee suit. It's easiest to do this if you have someone with you to check the back of your bee suit. A few feathers will do just as well, but the brush has long, soft bristles, which allow you to move the bees without harming them or making them angry.

Note pad and pen

You will find it enormously useful to take notes about what you have done in the hive and when, and if you have more than one hive it is absolutely vital. Record when you applied varroa treatments, and in some countries you are obliged by law to make a note of the manufacturer's batch number. Remember to be vigilant with your record keeping.

Above: *A bee brush is ideal for moving bees. Here the beekeeper is coaxing a swarm into a cardboard box.*

Useful items

The items described on pages 54–6 are essential, and you cannot even think about acquiring a swarm until you have bought them. There are, however, several other useful, but not essential, pieces of equipment, which you can obtain more gradually.

Disinfectant

Use a solution of a proprietary non-aromatic disinfectant to clean your hive tool, especially if you go from hive to hive or from apiary to apiary. If you are a member of a beekeepers' association there are umpteen opportunities for passing infection among members' hives and your personal stock.

Drawing pins

Keep a small stock of drawing pins to mark frames when you are working in the hive so that you do not forget where you last worked.

Forceps

Surgical grasp forceps are extremely useful and can be used to hold something shut so that you can handle it without having to keep up the pressure. They are particularly useful when you are dealing with queen cells because you can simply grab the cell, squash it and remove it in a single action.

Cap

Even though you will wear an all-over suit that includes a veil, it sometimes happens, especially if you are bending over, that the veil is pressed against your face, leaving you vulnerable to being stung through the mesh. In order to hold the veil away from your skin, it can be helpful to wear a peaked cap of some kind.

Bee paint

You will need to mark the queen with brightly coloured paint so that you can easily recognize her on the frame. This will considerably reduce the time you spend handling the bees (see also pages 88–9).

Rubber or cloth squares

The squares are cut so that they are the same size as the open top of the hive. You simply place a square over the exposed frames while you are working on something else or have to move away from the hive. The square keeps the bees calm and protects them from the sun or a sudden shower.

Bucket

You will find that a bucket is one of the most useful things you can have. Take it with you when you visit the hive and use it to hold the trimmings of wax that you might render down to make items from candles to soap.

Scissors

Some beekeepers trim the queen's wings so that she is unable to fly far from the hive, and if you do this you will not lose all your bees in the event of a swarm.

Queen cage

This is not something that a new beekeeper is likely to need, but you might be given a queen in a plastic mesh cage, plugged at the open end with some sugar candy or even newspaper. Introducing a new queen into a hive can be difficult – the workers might turn against her – but when she is slotted between the frames in the brood chamber while she is still inside the cage, the workers have time to lick the queen without harming her and are more likely to accept her. After a few days, when the workers have recognized her as their queen, you can either release her yourself or leave the workers to chew through the candy or newspaper to set her free.

Getting started

The most important question a new beekeeper must consider is where to site his hive so that the bees are safe from attack from both humans and animals and can, in turn, do no harm to neighbours or passers-by. You will probably have an ideal spot in your garden, but assess it carefully from everyone's point of view, and remember that once you have introduced the bees into the hive you will not easily be able to move it (see pages 90–1). Only then can decisions about acquiring a hive and finding a reliable source of a new colony of bees be made.

60 Where to keep bees

It is possible to keep bees almost anywhere – in ordinary gardens, on rooftops or balconies, beside agricultural crops, at sea level or up a mountain. Bees will happily live in the most unusual places, and in the wild they are more likely to be found in the cavity of a wall or in an empty chimney or unused drainpipe than in the newest, most sophisticated hive that money can buy.

Above: *A WBC hive on a garden patio with plenty of woodland cover behind.*

Choosing a site

The ideal site for a hive is, of course, a garden that is next to a field or an orchard, but as gardens have become smaller and houses closer together this is possible for fewer and fewer of us. Most beekeepers have to make the best of the conditions in their own garden, but with a little thought there is no reason you cannot keep a hive or two in even a comparatively small space.

When you are looking at the opportunities for positioning a hive or two in your garden, think first of all about the protection that your existing fences and hedges will afford the hive. Sheltering the bees from prevailing winter winds should be a priority, and a dense evergreen hedge is ideal. A high hedge or fence will also encourage your bees to fly higher, thus avoiding the heads of passers-by or neighbours. Although some beekeepers recommend positioning hives so that the entrances face south (in the northern hemisphere), in a sheltered garden this is less important than making sure that the openings face away from the prevailing wind.

Avoid low ground in the garden because in winter cold air tends to sink and gather in 'frost pockets', where the air temperature can be several degrees lower than in the rest of the garden. This will chill the hive and could lead to the death of the colony.

If possible, avoid siting your hive directly under a large tree. Not only might strong winds cause branches

Left: *A National hive with a sloping roof to protect from adverse weather conditions.*

and twigs to fall on the hive in winter, when your aim should be to keep your bees as quiet and undisturbed as you can, but also rainwater may drip on to the hive. However, in the height of summer a little shade over the hive will be welcome, so check the orientation of your garden and position the hive near to a deciduous tree or large shrub so that there is some shelter from the overhead midsummer sun but also so that any winter sun will fall on the hive and warm it.

Finally, make sure that you have easy access to the hive and that you have plenty of room to move around when you are working on it. Remember that you will need space around you to place the boxes that you remove when you inspect the hive, and you also need somewhere safe to put your smoker so that smoke doesn't constantly drift into the open hive.

Urban beekeeping

More people in the world live in urban areas, so the majority of us will be urban beekeepers. There are special problems associated with keeping bees in this type of environment, and the chief of these is pollution, which can degrade or even kill colonies. Sites near a factory or a main road are never going to be suitable, and if the only garden you have is affected by pollution but you would like to keep bees you will have to think about renting a site away from your house or keeping a hive on an allotment if you are lucky enough to have one.

Surprisingly, perhaps, the tops of tall buildings are good places for bees, although you will have to take extra care to protect the hives from strong winds and to make sure that you can take effective precautions against swarming: the cost of removing a swarm from someone's heating system could be prohibitive.

Unfortunately, humans can also be a problem. Your neighbours might simply be afraid of bees, so screening the hive with a high hedge that encourages your bees to

Urban bees

An important aspect of urban beekeeping is to be sure that you have gentle bees. Ask your supplier about the temperament of your colony. The gentlest bees, those who return to the hive quickly after they have been disturbed, are the best for bees that are kept in an urban garden.

fly high (see page 60) might be all you need do. Avoid looking at your bees when there are people about – especially when children are playing near by or when neighbours are sunbathing in their garden. When you do visit your hive make sure that you subdue the bees with your smoker and cover cloths and do not spend too long looking at them. Try not to shake dozens of bees out of the hive and keep them inside as much as possible. Take the time to explain to your neighbours how the hive works and how they can avoid being stung, and, of course, don't forget to offer them a jar or two of honey to thank them for their cooperation.

Vandals are, sadly, a fact of life. Try to choose a position for the hive that is out of sight of casual passers-by, and always secure the hive with a strap.

If your hives are at ground level make sure they are completely stable. Local pets, particularly cats, are quite heavy enough for a misjudged leap on to a hive to knock the whole colony on its side.

Providing nectar and pollen

Your bees will need a good supply of nectar and plenty of pollen from a wide range of plants to provide an adequate supply of food from early spring to early autumn. The availability of food is referred to as 'flow' – bees collect nectar and pollen as it flows from plants – and there are three main periods during the year. (See also pages 116–21.)

Below: *Oilseed rape is a favourite summertime crop for beekeepers as it is a good source of pollen.*

Spring flow

Although it is known as the spring flow, in most areas this period actually begins in late winter and lasts until early to mid-spring.

This is a time when fruit trees, including apples and cherries, are beginning to bear blossom, and some orchards still have their fruit 'top-dressed' (pollinated) by visiting bees. In addition, your bees will visit trees like *Salix* spp. (willow) and weeds, such as *Taraxacum officinale* (dandelion).

In later spring, if you live near or on a farm *Brassica napus* (oilseed rape or colza) and early legumes, such as beans and peas, will be important food sources. Oilseed rape is especially attractive to bees, but the honey produced crystallizes quickly, and remember that farmers are, of course, likely to protect their crops by spraying them with pesticides, which will harm your honeybees.

In built-up areas, although there will be a few early-flowering shrubs, such as viburnum, and spring-flowering bulbs, such as *Galanthus* (snowdrop), you will probably have to supplement your bees' food with syrup (see pages 80–3).

Summer or main flow

Leguminous plants, from clover to peas and beans, are a good source of pollen in the country, and in more urban gardens trees such as *Tilia* spp. (lime) produce pollen-rich flowers.

A great opportunity for beekeepers is the flow on the heather moors that lasts from midsummer until well into autumn. To take advantage of this, however, you must be able to move your hive, so avoid the WBC style.

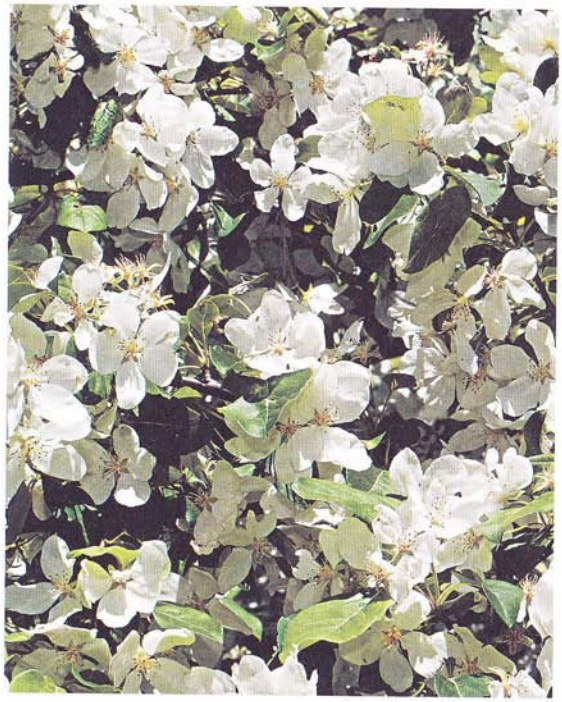
Autumn flow

In late summer to autumn many garden plants bloom in sufficient quantities to provide enough food for your bees. As well as different types of heather (ling) and all the many garden plants, *Hedera* spp. (ivy) are an invaluable food source.

Pesticides

Like all insects, bees are susceptible to being poisoned by pesticides, so you should not keep your hives where there is any likelihood that they will be exposed. Bees will, of course, travel a couple of miles when they are foraging for food, so it will not be possible to keep your bees away from all the possible dangers, but you should do your best to avoid droplet contamination.

Below: *During spring, flowering fruit trees are an excellent source of pollen.*



Acquiring a hive

Beehives are available from many sources, and your main difficulty will be in choosing the style you want and deciding whether to buy new or second-hand. Before you buy anything, however, talk to other beekeepers to hear about the pros and cons of the different styles and, if possible, arrange to see some of them in situ so that you can see how other beekeepers position and manage their hives.

Housing your bees

The main problem in keeping a hive of bees is that, to avoid losing your bees to a swarm, you need to have a couple of hives available, and the appropriate number of supers, as well as the associated frames, bases and stands. There may, therefore, be far more expense involved than you had at first thought.

Perhaps the best time to start a first colony is in the period after swarming, which is usually from mid- to late summer. This will give your new colony time to build up over the rest of the summer without the imminent threat of swarming. You will then be able to acquire the necessary kit over the winter months so that you are ready for the following season.

To house a single colony of bees in the new season you will need:

- 2 brood boxes
- 22 brood frames
- 2 queen excluders
- 2 floors and hive lids
- at least 2 super boxes with 22 super frames

Left: *A new National hive on a galvanized stand set in concrete, with a brood box, super and closed crown board, but waiting for its lid.*

Above: *A group of beekeepers learn the ropes under the supervision of experienced tutors – the best way to learn about beekeeping.*

Of course, you can get away with a single hive, which requires half this number of items, as long as there is someone from whom you might obtain a ready supply of extras if you need them.

A standard set-up for a growing colony at the height of the season will include: a brood box with associated varroa floor on a stand, a queen excluder and at least one (preferably three) supers with the appropriate number of frames. The first super will be full of honey for the colony's own stores to see them through the winter. Once it is full you can move the queen excluder above it and wait for the next super to fill, and so on.

What to buy

It is probably best to use the style of hives that are most widely available and in use in your area (see pages 44–7). If you are learning about beekeeping at a club or association it is advisable to buy something that you are already familiar with.

Second-hand equipment

It is only worth buying second-hand equipment if you know the conditions in which it has been stored and are certain that everything is in good condition. You must be sure that the hive has been thoroughly cleaned and scorched with a blowtorch before you put your new colony anywhere near it.

To avoid the transmission of diseases it is best not to buy second-hand frames. These are more difficult to clean and are awkward to dismantle to make sure that even the joints are completely disease and pest free.

The main incentive for buying second-hand equipment is cost. Modern polythene beehives are much cheaper than their wooden counterparts, and their use is increasing, especially among commercial beekeepers. However, they must be strapped to a stand that is secured to the ground – these hives are so light that you cannot just put a brick on the roof to stop it blowing over.

Many beekeeping associations sell equipment, and buying from them not only makes sure that you get a good deal but profits will go towards the club, encouraging beekeeping in your area. Better still, you will get a lot of impartial advice for free. There is also a worldwide network of beekeeping suppliers, most of whom are interested in the welfare of the bees themselves, so ask questions and get as much information as you can with your purchase.

Setting up a hive

Before you even think about acquiring a colony of bees, you must set up the hive correctly. It is almost impossible to move the hive once the bees are in residence, so take the time in the early stages to site and set up the hive so that you can plan carefully for the introduction of the bees.

Positioning the stand

Position the hive so that the entrance faces away from strong prevailing winds so that rain will not be blown into the interior. Make sure, too, that there is space for you to stand at either side of the hive while you work, rather than directly in front of it, so that bees can return from foraging without landing on your back.

The stand is an important part of the hive. It raises the working area and keeps the base off the ground. Hives that rest at ground level quickly fill with all sorts of pests, including slugs and snails.

Ideally, choose a stand that is made from tubular steel, which can be cemented into position. This allows you to hold the whole hive together with a strap, which is especially useful if you are using one of the modern, lightweight, polystyrene hives, but will also prevent the hive from being knocked over.

Left: *A mesh floor is now used as part of a varroa mite reduction strategy.*

Cold way or warm way?

To allow the air to circulate freely, set your frames the 'cold way', at an angle of 90 degrees to the entrance. To reduce air circulation, set your frames the 'warm way', parallel to the entrance. Use the warm way if your hive is in an exposed site and the cold way if it is in a sheltered position.

Establishing the nucleus

Bees that are bought usually come in a nucleus, often known as a 'nuc'. This is a box with four or more frames of brood, some stores of honey, a marked queen and a host of attendant workers. Your first task is to place the frames of brood in the centre of the brood box and pack in new frames on either side.

When the bees are in the brood box, place a super on the top and a feeder with 2:1 syrup solution (see pages 80–3). Then you should leave the hive alone.

After a week you can take a peek inside to see if the queen is laying and if there is evidence of worker bees flying about and collecting honey and pollen.

As the grubs appear in the brood you will notice that the new frames are being drawn out built with comb and that the size of the colony is increasing. You can then place a queen excluder and a super of honey frames on top of the brood box. This super, when it is full of honey, will represent the bees' winter supplies.

You can place another super on top of this – this will be your honey – only when the bees have filled the first super with honey. You must make sure that you cater for their needs before you think about your own wishes.

Below: *A super with ripening honey and bees drawing cells on the crown board. This colony might need a new super for more room.*

Acquiring a colony of bees

If at all possible, buy your bees from a reputable breeder. Every association will be able to put you in touch with several suitable breeders, and only by acquiring bees in this way will you be able to plan for the introduction of the bees. Decide where you are going to keep them, where you will put and organize the hive and so on before you even think about buying the bees.

Choose your bee type

The best way of making sure that you get the most suitable bees is to talk to other beekeepers – ideally several. You need to choose a hybrid or type of bee that will do well in your own particular environment. You might, for example, have plans to take your bees to various locations to take advantage of the flow of honey in different areas, and you will, therefore, need a bee that is suited to the range of conditions it will encounter.

As a new beekeeper you will need a colony that will put up with your mistakes, will not surprise you with untoward swarms and mess up the hive with lots of brace comb (wax bridges between adjacent surfaces). Above all you are looking for well-behaved, gentle bees.

Before you buy, ask the supplier:

- Are they good mannered?
- Do they swarm easily?
- Is the queen prolific?
- What race or subspecies of bees do they come from?

You will be able to assess their suitability for your apiary and conditions by asking your supplier who else has this type of bee. You might also want to know how many colonies the supplier collects queens from, so that you can be confident with their techniques, and remember to ask if there have been any recent problems, information that will minimize the likelihood of your bees having any diseases.

It is possible to order a nucleus through the post. Make sure that you are around and able to respond the moment the bees are delivered.

Timing

Make sure that you have everything ready for your bees before you buy them. You do not want to leave them packed into a brood box for very long, and 24 hours in hot temperatures might kill them.

Consider whether you will need help in putting your bees into the hive – if it is the first time, having an experienced beekeeper on hand will give you the confidence you need even if you don't ask for their assistance – but you will need to coordinate the dates.

Also, make sure you have a good supply of food for the bees. It might take many days for bees to collect nectar and pollen, and even longer to make this food available for the colony, so the golden rule is *feed them*.

Accepting a swarm

Occasionally you have no option about setting up your hive. Someone descends on you with a box of bees because they have heard that you wanted some and they were given a swarm – and here it is!

If you are a newcomer to beekeeping get help when it comes to taking on a swarm. You might be taking a weak swarm, a swarm of an old queen that might not last the winter, or a set-off of diseased bees. New beekeepers should only accept a swarm if they have reliable back-up. Nevertheless, housing a swarm of bees can often prove successful – but keep your expectations on hold a little until the colony is well established.

Swarms are usually taken by placing a box or an old-fashioned skep over the swarm or, if the bees are on a branch, by cutting off the branch or shaking the swarm into the box or skep (see pages 86–7).

Above: *A nucleus box with four brood frames ready to place in a new hive.*

The simplest way of introducing a swarm into a hive is to shake it from the box into a brood box half-filled with brood frames. However, it is more interesting to 'throw' the swarm into the hive as described on page 87. Bees always walk upwards into the hive.

Bee care

As with all animals that humans have 'domesticated', from pet mice to horses and ponies, the beekeeper is responsible for his bees' wellbeing and for making sure that they have sufficient food and drink and that the hive is secure and well made. The beekeeper is also responsible for keeping his bees healthy and free from pests and diseases, and the best way to do this is to establish a system of regular checking. Once you have become used to your bees, however, you will find that this routine becomes an enjoyable experience.

72 Inspecting the colony

Part of your summer routine will be to inspect your bees to assess their health and to make sure that the queen is laying eggs and the worker bees are making honey and capping cells. You should check the hive at least once a week in spring and summer, and then reduce this to once a fortnight as the days begin to shorten and temperatures drop in early autumn.

Above: *Regular inspections of the hive in the summer are important, but they should be of short duration.*

Checking the hive

You can, of course, tell if a colony of bees is healthy simply by checking inside the hive, but you should be able to get some first impressions before you remove the lid. You should see a large number of bees – a handful every few seconds – flying in and out of the hive. They should have a determined path and alight on the board and march straight inside. You will not be able to see if the bees are full of honey, but the pollen sacs on their back legs should be visibly full of yellow, orange or white pollen, and they will look dusty.

If you knock on the hive and get the response of loud buzzing and the bees appear haphazard and fairly angry it is likely that the queen is dead or missing.

Opening the hive

You should only enter the hive when the temperature is above 15°C (59°F), it is not raining heavily and the wind is light. Do not chill the bees at all.

Avoid opening the hive more frequently than is absolutely necessary. Bees are not pets, and if you examine them too often you will lose them. In summer, when the bees are active, you should check them once a week, but in late spring and early autumn once a fortnight will be sufficient. In winter leave your bees alone, although you should, of course, continue to check the outside of the hive for security and signs of predation.

Looking inside the hive will normally give you an indication of the colony's strength, how much food they have or might need and the health of the queen. You will be able to judge if you need to take any remedial action, add a super, give some food, remove queen cells, re-queen and so on. You will also be able to check the colony for signs of disease.

The first time you open your own hive can be a nerve-racking moment. Many newcomers to beekeeping like to ask a more experienced person to accompany them – just in case. Keep calm and prepare yourself in a logical

way. Put on your bee suit, find your smoker and make sure you have matches or a lighter. Put the spare frames and supers close to hand.

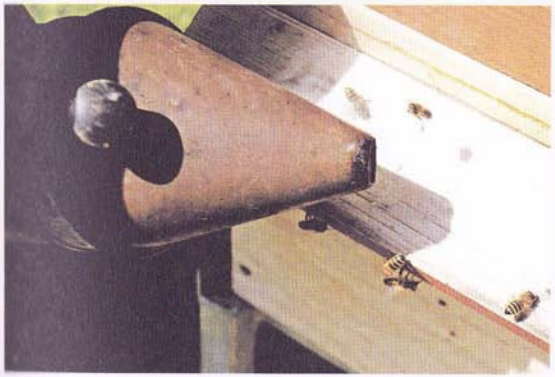
When you light the smoker avoid pumping the bellows as if it were a steam train. It will get too hot, and the fuel will burn too quickly. Give a couple of short puffs away from the hive to make sure that it is still alight, and only then should you approach the hive.

As you open the hive take care that you do not accidentally kill any bees. When a worker bee is in distress she gives out an alarm pheromone that will be ignored by most of the bees. However, if several bees are injured or distressed the alarm increases, which will have the effect of making the other bees more prone to attack. You will notice bees flying straight at your visor. Try to stay calm if this happens, and try not to breathe heavily because your breath will excite them even more.

The usual set-up of a hive is to have a super on top of a queen excluder and then a super for the colony's stores and then the brood box. You might have added a queen excluder above the colony stores super if it is full of honey, and the queen is not likely to lay in this.

How to open and check the hive

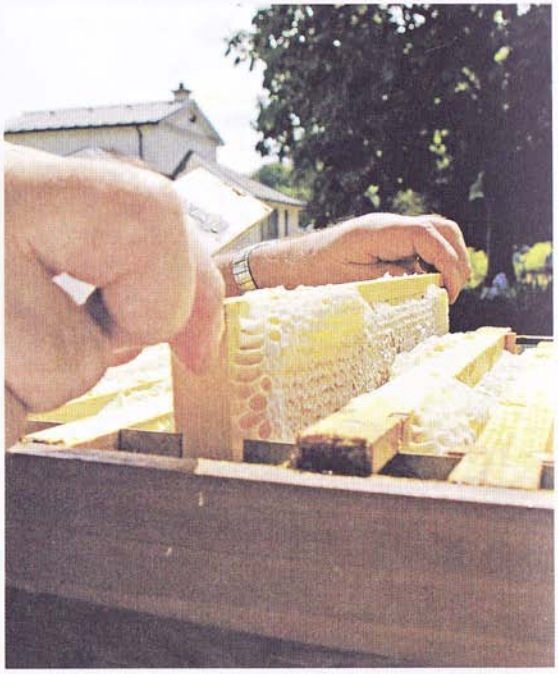
Opening the hive should become a ritual that you always stick to. A good routine saves mistakes and trouble later.



1 Make sure your smoker is properly lit and delivering good quantities of smoke. Remember not to stand directly in front of the bees' entrance, then puff the bellows to deliver a little puff of smoke into the hive from below. Do this before you remove the lid. The smoke warns the bees of fire, and they will start to take honey, which makes them more rotund and less likely to sting (though it is by no means certain).

2 Remove the lid and put it upside down to one side of the hive. You will stack the other components on top of this, except, perhaps, the crown board and queen excluder, which you might like to place on the other side of the hive.

3 Deliver another puff of smoke underneath the crown board as you lift it. If there is no queen excluder in the hive, carefully lift up the crown board and look on the underside to check that the queen is not there. If you forget to check and quickly put down the crown board there is a danger that you will kill the queen (this advice applies equally to the lid of the hive and to the queen excluder itself). If you see the queen carefully coax her back into the brood box.



4 Because the queen occasionally gets through the excluder (see page 27) and lays in the smaller honey frames check these frames before you remove any of the top super boxes to make sure there are no eggs or grubs in the cells.

5 Use your hive tool to lever a super from the hive. Do not try to lift it by the frames. Instead, grasp the sides of the box firmly and lift it up, keeping your back straight.

6 Gently prise up one edge of the queen excluder with your hive tool. Never try to force it or bang on the side of the hive to loosen it. Check the underside of the excluder for the queen. If there are a lot of bees on it, shake them off into the hive with a deliberate single sharp movement. Repeat this if they do not come off. Lay the excluder down by the side of the hive.

7 Carefully remove the brood frames and check for the queen, healthy grubs and capped brood cells.

Left: *Making notes is important – the best place to keep them is inside the hive itself, especially if someone else is to enter the hive at a later date.*

In the brood box

When you have opened up the brood box look for the queen. A gentle puff of smoke will send the bees on the surface of the frames scurrying out of the way so that you can gently lever out the frames. Hold each frame over the brood box as you inspect it so that if the queen falls off she will land back in the box.

If you can find the queen so much the better. This is much easier if she is marked, which has the additional advantage that you can colour code the marking to indicate her age (see pages 88–9).

If you can see lots of eggs in the cells then you can be sure that the queen is there – unless, of course, there are lots of drone cells, which might mean the queen is running out of sperm. In general, however, a large number of eggs in the height of the season is a sign of a healthy colony.

If the colony is strong you will be able to see many bees, all of them busy and moving with purpose. The laying queen will be surrounded by workers, and you will find that each of the frames has a central brood area with capped and uncapped cells. Surrounding these are the storage cells with capped and uncapped honey. There will also be plenty of cells containing pollen, which is used for food. These cells are uncapped, and usually only one type of pollen is stored in each cell – you will be able to see the orange, yellow and white accumulations, which are often the work of a single bee.

If you have one of the new polystyrene beehives, the queen will lay right to the edge of the frame because she detects that the hive is better insulated and therefore warmer.

At the height of the season the number of bees will have increased to around 30,000 individuals, and as the queen continues to lay you have to be sure there is enough room. The queen must have sufficient drawn frame to continue to lay to maintain the growth of the colony. Otherwise, the queen might leave the hive to look for more comfortable accommodation. Make sure that there are frames to be made up in the brood box so that the colony can expand and check that once the super is full of honey there is another on the top to be drawn.

If the brood box is full and you are worried about the amount of space, you could add a super to the brood box without the queen excluder. This will give the colony extra space, which might be necessary if the weather is good and there is a plentiful flow of honey. In a disastrous year, on the other hand, you will have to feed your bees, even during the summer.

Rebuilding the hive

Return the frame that you laid outside the hive to its original position so that the box has its full complement of frames, then you can rebuild the hive, replacing each element in reverse order it was taken down and in such a way that you preserve the bee space. This means that you must position the queen excluder so that the 'gap' or bee space is the right way round – either at the top or bottom of the frames, depending on the type of hive. The same goes for the crown board, but you can get boards with a bee space on either side.

As you put the hive back together, for instance when positioning the super, excluder or another box on to the box containing bees, give them a little waft of smoke before carefully laying the box at an angle over the frame and then slowly twisting it into position. You are less likely to kill bees if you do this.

Take care too, as you are about to put a box with bees in it back on to a lower one, that you check that you do not have a pyramid of bees hanging from the uppermost box. To avoid crushing them as you lay down the box, gently shake them off and puff a little smoke to drive them away. Smoked bees usually climb downwards.

Paperwork

Don't forget to keep your notes about each hive up to date. A favourite place for keeping notes about a particular hive is in a plastic wallet attached to the top of the crown board. Keep a note of all the jobs you have done in the hive, such as adding supers, and whether you have seen the queen and eggs and brood. Keep a record, too, of any treatments you applied and the dates.

Above: *Always rebuild the hive completely and fasten up with the strap before starting work on the next hive.*

Checking frames

When you open a hive you should take the opportunity to check the frames. Before you remove any frames from the hive make sure that there are no bees on the top bar, especially where the top bar sits in the frame. Usually, the bees will have propolized the frame into position, so use your hive tool to loosen both sides of the frame before you lift it out.

Lifting the frame

Once you have removed any brace comb from the frame and have loosened it with your hive tool, carefully lift the frame from the box. It should be covered with bees, and they will begin to walk over your hands as they try to work out the change in their environment.

Below: *Always lift the frame out of the box vertically and grab it by the lugs.*

Examine both sides of the frame without loosening your grip on the top bar. This is an important skill to learn: do not be tempted to lay the frame anywhere other than in its correct position in the box. If you drop it you will be covered in a few hundred angry bees and run the risk of killing the queen should she be among them.

The base of the frames are frequently propolized, and you often find some comb drawn on the base. Clean this away with your hive tool and remove any wax on the top

Brace comb

Sometimes you will see what is called brace comb between frames. This is wax built by the bees between the frames to stick them together. If you look down vertically between the frames you will be able to see the comb, which is easily separated with a knife or hive tool. Brace comb contains no grubs, so you can break it with a clear conscience.

bar. If your hive tool meets some resistance on the underside of the frame, do not force it. It might well be a nail or, worse, some of the wire inside the foundation. Work carefully because you do not want to tear open the grub-filled cells.

Queen cells

Swarming and re-queening hives are discussed on pages 84–7 and 88–9, but when you are carrying out a general inspection of the frames you might find queen cells in one or both of their typical positions.

If you find some queen cells in the middle of a frame then you need to check on the health of the queen. She might well be dead or not laying properly because these are emergency queen cells. You might also find queen cells that fall from the bottom of a frame and hang vertically; these are built in response to a failing queen or overcrowding.

If you know that your queen is young, fertile and healthy you should remove the queen cells. At the same time make sure that there is plenty of room in the hive for the queen to lay more eggs by adding another box. If you are uncertain about the age and status of the queen you should seek the help and advice of a more experienced beekeeper.

Egg cells

When you check a frame the presence of eggs will prove that the queen is working well. Studying the position of the eggs will enable you to work out how long ago the queen was last laying on any particular frame. Day-old eggs are glued vertically to the base of the cell. By the second day the eggs will have fallen over to an angle of 45 degrees, and on the third they lie flat on the bottom.

Recognizing a failing queen

A queen that is laying well will place her eggs in the warmest part of the frame, usually laying from the centre outwards. Her first working of a new frame will be in the centre, and these cells will be the first ones to be capped by the worker bees. In a circle around this you are most likely to see uncapped brood, and these cells will be surrounded by cells filled with stores, first pollen and then honey, which are set as arches around the central brood. (If you have a polystyrene hive remember that the queen will lay right up to the edge of the brood frame because of the extra insulation afforded by the hive walls.)

A failing queen will not lay in a uniform way. Some cells will have eggs in them that are not viable. The capped brood will then have 'holes' in it where the queen has missed. When the cells look patchy and weak the colony is in danger from the reduced numbers, and worker bees will set in motion the process of replacing the queen bee. This process is known as supersedure (see page 88).

Checking a frame

While you are holding the frame look for the queen. Marking her (see pages 88–9) makes this easier.

If the queen is not on the frame shake down the majority of the bees from the frame into the brood box. A sharp, deliberate downward movement ending in a sudden upstroke of your hands should dislodge most of the bees.

Shaking down the bees will reveal the face of the frame. Look at the brood areas, with eggs and grubs and capped cells check the outer honey storage areas with the odd cell of pollen. If you see eggs you will know that the queen is working well.

Carefully lay each frame back into its original position or into a spare box beside the hive as you continue your inspection. Always replace the frames carefully to avoid killing any bees.

80 Feeding bees

There are several times during the year when it will be necessary for you to give your bees a helping hand and provide them with food.

Why feed?

You should be prepared to feed your bees at any time of the year, and although there are three main periods when they are likely to need feeding, be ready with food during a cold, wet summer and whenever you have removed honey from the hive.

Above: *You can feed sugar syrup to your bees using a large bee feeder on top of the hive.*

Food is scarce

Winter is clearly a time when bee colonies may be hungry. Even though there are drastically fewer bees in the hive at this time, they consume huge quantities of honey: about 18 kilograms (40 lb). In winter each bee takes more than its own body weight of honey every couple of days.

In spring a young colony might not have sufficient flying bees to gather enough food from the environment, and feeding the hive with sugar will allow the colony to build up a brood. Creating wax requires large amounts of energy, not least because the wax itself has a very high calorie content.

Eventually, the working colony will find equilibrium between gathering bees and house bees so that food can be stored and the young tended, but at the beginning and end of the season the colony is vulnerable, and the bees have to be fed.

Autumn feeding

You will also need to feed your bees if you have taken honey or if there is not sufficient honey in the hive. It takes the bees a couple of weeks to create honey from sugar syrup and then cap it. The honey has to be matured by evaporation, otherwise it might well ferment in the cells and this would be disastrous.

You should only stop feeding the bees if they are no longer taking down the sugar or if winter sets in, which in practice means no later than mid-autumn. Make sure there is plenty of room for the bees to place the syrup into the cells.

Feeding honey

You should not give honey to your bees unless you are sure of its origin and disease status. Imported honey tends to contain nosema and foul brood spores, so be cautious.

Spring feeding

When the temperature begins to rise in spring, honeybees start to forage. This can be very early in the year, and often the natural supplies of nectar and pollen have not started to flow properly. Although bees rarely starve in winter, they are quite likely to starve in spring. Giving your bees some sugar syrup on warm spring days will allow the colony to make stores that will then enable them to keep pace with the expansion needed to take advantage of the late spring and early summer flow of available food.

Sugar syrup

The recommended standard for making sugar syrup is to use the ingredients in the proportions of 50:50.

Put 500 ml (17 fl oz) water in a large saucepan and heat it to boiling point. Turn off the heat and once the boiling stops stir in 1 kilogram (2 lb) granulated sugar. Keep stirring until the sugar has completely dissolved. When the liquid has cooled it should be clear. You can then transfer it to a bee feeder.

If you use more diluted syrup you will find the bees will need more time for it to evaporate before capping. Moreover, it might cause digestion problems and premature voiding of waste products because of the volume of liquid being taken by the bees. There is also some evidence that using unrefined or brown sugar in the syrup can induce dysentery in bees.

Because the syrup is odourless, you can make it more attractive to the bees by adding a little honey to the hot liquid. Make sure you add the honey when the water is very hot so that it kills any nosema spores or bacteria it may contain.

Do not put your finger into syrup to test the temperature. When sugar re-crystallizes the process gives off a lot of energy in the form of heat, and there is no burn worse than one caused by hot syrup, because as the liquid cools on the skin, sugar crystals continue to give off heat.

Sugar candy

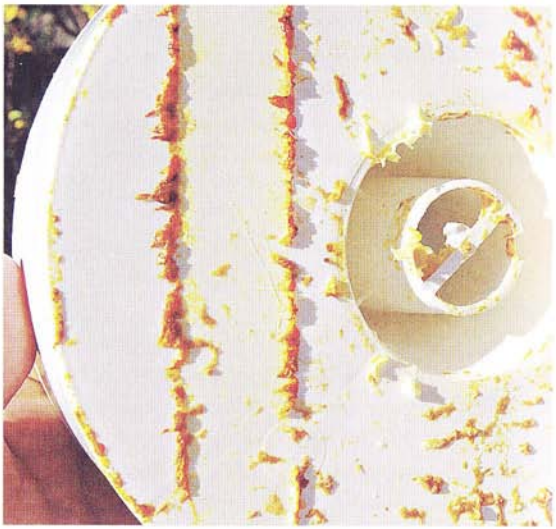
Bees are not usually given candy, although it can occasionally be used in winter. Candy is used to make plugs for the bees to eat through – in a queen cage, for example (see page 57). You must provide water to help them get through the candy, otherwise they run out of spit to dissolve it.

Candy is made from a 5:2 mixture of sugar to boiling water. Once the sugar has dissolved, heat the mixture to 115°C (240°F) and pour it into moulds. It should set into a cake-like form.

Robber bees

Bees will rob each other of their stores, and this tendency can be exacerbated by making it obvious that there is sugar in the hive. The bees will give themselves away by flying around in an excited manner, and any bee that is already in the hive from another colony will soon communicate the presence of sugar syrup to its own hive. It is best to feed syrup towards dusk, thus reducing the likelihood of robbing, because bees tend to forget overnight. If robbing is a problem you should reduce the hive entrance so that your bees can defend it more easily. Take care that you do not spill syrup outside the hive because it will simply encourage others to explore the hive, particularly wasps, which will kill individual bees.

Above: *A circular feeder is common and inexpensive and holds nearly a litre of syrup.*



Above: *This feeder has been placed directly on frames and the bees have glued it in position with propolis.*

Types of feeder

There are several types of feeder, and your choice is really a matter of personal preference or what is readily available.

Circular feeder

This is probably the most common form. It is cheap and easy to keep clean, but take care that you do not lose the central cup. The circular feeder holds about 1 litre (1¾ pints) of syrup. Inside there is an inverted plastic cup that restricts the bees' access to the liquid. Never use this type of feeder without a cup, and if you cannot find it use a honey jar instead.

The feeder can be placed on top of the crown board if it has holes in it, but it is actually better placed on top of the frames themselves so that bees can gain immediate access. It also cuts down the possibility of robbing by way of an ill-fitting lid. If you place this feeder on the crown board it will often fit under the lid, but if you put it directly on the frames you will need to put an empty box around it in order to close the hive. Of course, if it is placed on the crown board feeding hole then you will be able to fill it without disturbing the colony.

When you first put the feeder in position, dribble a little of the syrup down into the hive to gain the bees' attention and interest.

Contact feeders

This type of feeder, which is less popular than it used to be, is usually rested on the crown board. The jar is set upside down, and the lid allows the syrup through very slowly so that the bees can take the syrup. They are also able to speed up the flow by sucking hard.

Changes in the ambient temperature when the contact feeder is almost empty can cause the air inside the feeder to expand, causing a flood of syrup. You also need to keep an eye on it because once it is empty the bees tend to propolize it.

Frame feeders

This feeder is a box that is fitted in the brood box. It is the same size as a frame but is hollow, and there is a series of ledges and wire mesh inside to stop the bees from falling in and drowning. It is not suitable for winter feeding because you will need to open the brood box to fill it and this will chill the bees.

A frame feeder is the only effective method of feeding bees in top-bar hives.

Tray feeders

This type of feeder, which is used for the large-scale feeding of colonies, sits on top of the brood box. The tray will hold 2 litres (3½ pints) or more of syrup and allows bees access at one end. Tray feeders are built to fit into specific types of hive, so check that it is appropriate for your hive before you buy one.

How much food do bees need?

In order to get it through winter a strong colony will need about 15–18 kilograms (34–40 lb) of liquid feed. Each brood frame weighs about 2 kilograms (4¼ lb) when it is filled with capped honey, and a simple calculation will show that if all you have after the summer harvest of honey is a brood chamber full of capped honey this will hold about 22 kilograms (48 lb). But it is more than likely that the brood chamber is not completely full of honey at all. In addition, there will be an amount of pollen to take into consideration.

You will find that experienced beekeepers can lift the sides of the boxes (a process known as hefting) and know – apparently instinctively – how much food is available for their bees. You will do better to count the frames and work it out more accurately.

A super frame holds just over 1 kilogram (2 lb) of honey. You will therefore get 11 kilograms (24 lb) of honey in a full super, so a brood box and a super together should be enough to get a good colony through the winter. Check the weight of the hive by lifting and seeing how heavy it is.

Do not just assume that the colony has full brood frames: inspect them. You can then add the appropriate amount in late summer, remembering that there should be enough space for the bees to store all this feed and evaporate the water prior to capping.

Feeding pollen

Pollen is one of the bees' main sources of protein and fat, and it is also an important source of minerals. It has been calculated that to raise one bee the colony needs 100 mg of pollen. An average colony will gather around 50 kilograms (110 lb) of pollen to feed itself. Pollen is almost entirely used in rearing brood, but it is also important in stimulating the bees' hypopharyngeal glands.

The availability of pollen is not uniform, and in some countries it has been necessary to feed substitutes. Various materials, such as fish meal and soya flour mixed with sugar syrup, and sometimes a little egg yolk, have been used successfully. Most new beekeepers will not encounter this problem, and where it is necessary local beekeepers will have their own recipes that you should follow. Ultimately, you should try to grow plants that will produce a natural source of pollen.

Water

Make sure that your bees have access to water all year round. If you have a natural garden pond you will notice your bees in the shallow, warm water at the pond's edge. If you do not have a pond near the hive you must arrange a source of water.

Although you can buy some purpose-made water fountains, simple arrangements of gravel-, moss- or peat-filled dishes topped up with water are ideal. Set several of these dishes around the hive and in your garden.

Swarming

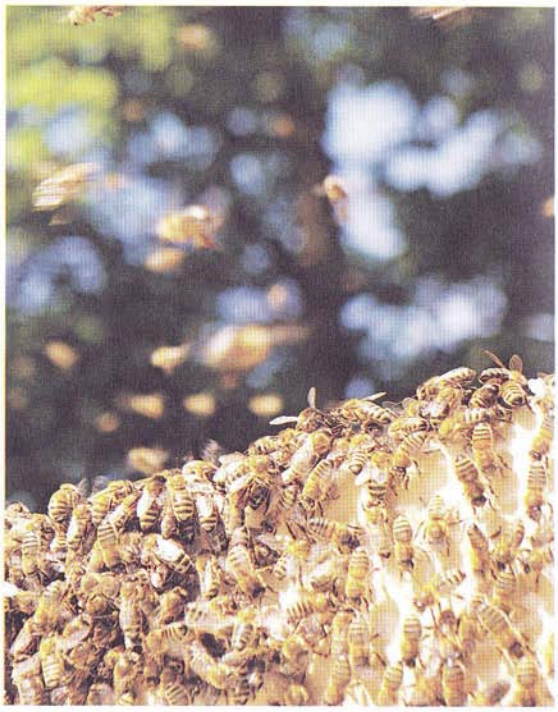
People are afraid of swarming bees for many reasons. If you are an urban beekeeper you are automatically in the spotlight if thousands of bees are flying around the neighbourhood and landing in gardens. But the primary reason beekeepers fear swarming is that the colony that remains is frequently weakened, leaving less honey to harvest.

Why bees swarm

Most of the books describe swarming as the bees' way of forming more colonies, but this is only part of the reason. Swarming is, in fact, part of the lifecycle of the honeybee, and without it bees will not evolve further. As it is, the exchange of genetic material between bees takes place only every couple of years, and for this reason the honeybees' evolution is slow in comparison to predator insects and bacteria.

It is not possible to keep bees and make honey without mating a queen, and so the bees' sexual reproduction, during which the bees' characteristics are passed on to new generations, are part of the beekeeper's work. Fortunately for humans, subspecies of honeybees are genetically similar to each other, and so it is possible to hybridize bee populations to create strains of bee that have nearly all the qualities we would want, and nearly all the bees we keep around the world are hybridized to some extent.

There is sometimes no explanation of why bees swarm. You might well have the perfect colony, but the queen seems intent on vacating the hive. Should she repeatedly attempt this, it is probably advisable to re-queen altogether (see pages 88–9). This is a technical process for which a beginner may need to seek help.



Above: *A swarming colony alighting on to a cardboard box. You could also use a skep to collect the swarm, if you have one.*

Drones

Although they are often regarded as the unproductive members of the hive, drone bees are the driving force of a healthy bee gene pool. A hive may contain a few hundred drones, and each of these will have produced several hundred thousand sperms, each of them genetically different, and some perhaps with a beneficial mutation in the DNA that may make the bee a better gatherer, flyer, breeder, defender or survivor of varroa or another bee disease.

The numbers of drones will increase in spring as part of the natural routine of the hive, and at this time you should check the frames for queen cells, especially if your queen is greater than two years old.

Queen cells

The presence of queen cells in late spring is a sign that a colony is preparing to swarm. The two types of queen cells that may be seen (see page 79) might not be solely a response to an ageing queen. The colony might feel it is overcrowded; it might not have had enough stores to survive through winter without hardship; or the colony might be living through a prolonged period of bad weather.

Recognizing queen cells

You can recognize a queen cell by its unusual shape. It looks like a cased peanut protruding from the frame, either in the centre or at the bottom of the frame. Interestingly, the two types – centre or bottom – are built as a response to different stimuli.

The centre or supersedure cells are created in response to a failing queen. She might be old or ill – perhaps suffering from nosema or bee dysentery – and the supersedure cells are there to create a replacement queen. If you find them in your hive you may want to look closely at the queen's health.

The bottom or swarm cells are there to create a second queen to divide the colony, leading to more hives. It is a natural reproductive stimulus to create more bees.

Above: *When bees swarm, the queen is of prime importance and the workers fuss around to make sure she is neither lost nor damaged.*

Preventing swarming

If your queen is healthy and laying and is less than two years old you may wish to take steps to avoid the likelihood of swarming.

Remove queen cells

You can simply remove the cells with your hive tool. If there are no competing unmated queens your current queen is less likely to swarm.

Add a super

In mid-spring add a super to give the colony room to store the supplies that are now beginning to flood in.

Check the brood box

Make sure that there is plenty of space in the brood box for the queen to lay eggs. It is unlikely to be completely full in early spring, but you could add a super as a secondary brood box if you're really worried.

Above: *A queen marked on the thorax. She also has her left wing clipped.*

Clip her wings

You can prevent the colony from going more than a few feet by clipping one of the wings on the queen. If she cannot fly very far the rest of the bees will not wander far either. Be careful though, because queens that have had their wing clipped are often found on the floor in a swarm – a very vulnerable place to be.

Artificial swarm

If the queen is older than two years old you may consider making an artificial swarm. This is an easy technique to master and is usually successful. In the end you will have two colonies of bees instead of one, for nothing more than the cost of the boxes and frames needed for the new hive.

Move your hive so that it is about 4 metres (12–13 feet) away from its original position and set up a new hive in the old position. Put about seven brood frames in the brood box, preferably with a couple of them having already drawn comb so the queen can get an early start laying eggs. If necessary, introduce a frame of brood from the original hive that has got unfilled cells on it. Some of the immature adults on that frame will be able to make an immediate start with undrawn frames.

Make sure there is space in the centre of the new brood box for a frame that you will transfer from the original hive. This frame must have the queen on it and no queen cells.

By this stage you will have a hive with a couple of frames of brood and a queen, and a hive with queen cells and a lot of bees and some brood waiting to emerge. You can remove the majority of the queen cells in the transferred hive. The first queen to emerge will mate and kill the others anyway.

All the flying bees that are in the transferred hive will naturally return to the hive that they recognize as home, so in the following hours the old queen will have most of her entourage back with her. The transferred hive will be queenless for up to a fortnight, but will accept the new queen once she has emerged.

It is a good idea to feed both the colonies of bees as a part of the artificial swarm process until they are freely foraging for nectar and pollen.

Introducing a real swarm

The swarm is a nightmare for beekeepers and something to be avoided at all costs among your own bees, but at the same time a swarm can be a gift when it appears – a colony for free.

Taking a swarm is not easy: you are, in effect, taking on someone else's bees. It is likely that the queen is older and has escaped for her life from a colony that has produced a viable new queen, and you have no way of assessing the qualities of the colony. Moreover, it is a distinct possibility that drones from the swarm colony could mate with new queens in your existing hives, thus introducing some of their traits into your stock.

You may find that your own bees swarm, and you are able to recover them yourself. This is especially true if your queen's wing is clipped because she will never get more than a few feet from the hive, so you will have to introduce your own swarm!

Collecting the swarm

Make sure that it is safe to recover the swarm – bees often settle high up in trees or on roofs. Then collect the swarm in a cardboard box or, if you have one, a skep (see page 44). Put the box or skep on a white sheet on the ground and give the swarm time to gather into the box. Some beekeepers bait the box with honey or even use pheromone sprays to attract the swarm, but this is rarely necessary.

When the bees have settled check for the presence of the queen, then transfer the swarm to the hive. If the swarm is small it may be possible simply to pour the bees into a brood box with the four centre frames missing but with at least a couple of drawn frames for the queen to inspect and begin to lay in. After a day you can inspect the swarm and close up the brood frames and fill the gap to complete the box.

If a fellow beekeeper can show that the swarm belongs to him you should allow him to take the bees back to their hive. Ask around before you finally secure them as your own.

Above: *Encourage as many bees as you can into the receptacle you are using.*

Throwing a swarm

This is a job for two people and should not be attempted alone, particularly if you have never done it before. Attach a wooden platform to the entrance of the hive to form a ramp and secure it so that it cannot slip. Spread the sheet, with its box of bees, over the ramp so that some of the stragglers on the sheet can gain access to the hive, which can be baited with a little honey if required.

Take the box and carefully but firmly pour the bees from the box on to the sheet towards the entrance of the hive in a single movement. The word 'throw' is perhaps a little harsh: you do not want to kill the queen by throwing them with too much force. You should then see the bees start to walk along the cloth into the hive, with the bees at the entrance fanning their scent to those below. This encourages the rest of the bees to process towards their scent and as more bees enter the hive, the strength of the pheromones increases.

Above: *Gently throw the bees on to the sheet-covered ramp that leads to the entrance of the hive.*

Re-queening

The process of removing a queen and replacing her with a new one is called supersedure, and it should be done every two years. Re-queening ensures that the vigour and laying rate of the queen are as high as possible, and reduces the likelihood of swarming.

Natural supersedure

When a queen cell is allowed to develop into an adult virgin queen the process almost invariably leads to the old queen taking off in a swarm. This can be avoided by killing the old queen and removing all the queen cells but one. The new queen will emerge a week or so later, by which time the bees will be ready to accept her. She will mate and start her work.

Alternatively, you can buy or rear a replacement queen, introducing her to the hive in a queen cage (see page 57).

Supersedure should take place only when there are enough drones to inseminate the new queen, and this is usually the earlier part of winter. A barbaric-sounding method of forced supersedure is to clip off one of the hind legs of the old queen. She will not be able to place her eggs correctly, and the workers will realize this and start to prepare a new queen cell. They will then kill off the old queen by balling her, a process that involves a number of bees attaching themselves to the queen and increasing their body temperature until she dies from heat exhaustion.

Marking the queen

The life of the beekeeper is so much easier if the queen is clearly visible. She should, therefore, be marked. Putting a dab of white paint on her back will not only tell you where she is, but if you change the colour each year you can also easily tell how old she is. This isn't necessary for new beekeepers, who have only one hive, and nor is it essential if you keep proper notes in the hive. However, if you catch a swarm and the queen is marked you will immediately know quite a lot about the bees.

How to mark the queen

When you have identified the queen, catch her in your fingers and dab her with some quick-drying paint in the appropriate colour. This is not as easy as it sounds, and the procedure takes considerable experience. The queen is delicate, so you can easily damage her. Her legs are particularly important because she has to be able to

Colour coding for queens

The internationally agreed system of colour marking means that wherever you get your bees from or send them to will have the same system. Because a queen is rarely kept (or lives) for longer than five years the system repeats itself every five years.

- Year ending 0 or 5 – blue
- Year ending 1 or 6 – white
- Year ending 2 or 7 – yellow
- Year ending 3 or 8 – red
- Year ending 4 or 9 – green

squat into a cell to lay her eggs, and if she is injured she will not manage this.

The easiest way is to buy a queen cage, which is a trap that can be placed on top of the queen. You can mark her through the bars using a brush or matchstick coated in paint of the appropriate colour. Some beekeepers use special bee paints, while others use model-makers' paints.

Above: *A queen bee has been marked with yellow paint, indicating how old she is and making her clearly visible to the beekeeper.*

Moving a hive

There are several reasons for having to move a hive – you could be combining two colonies, for example, or moving your bees to a better food supply – but this is something that has to be done with great care and only after thorough preparation.

If you move the hive just over 1 metre (about 3 feet) the bees will congregate where the hive used to be and will take a long time to find it, sometimes too long, when the bees will die. Bees normally forage up to 3 kilometres (almost 2 miles) from the hive, and if the hive is moved within their familiar area they will fly back to where the hive used to be and will not find their new home.

If possible move the hive at dusk or dawn, when all the flying bees are inside the hive.

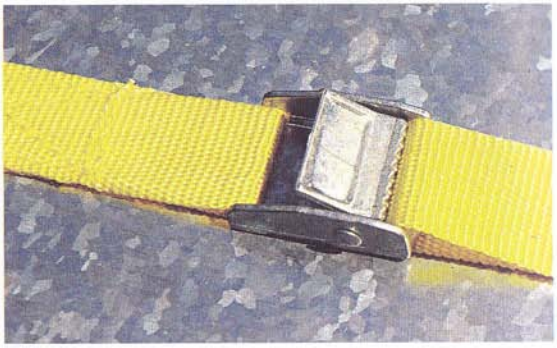
If you need to move a hive within the space of the apiary, simply move the hive a little less than a hive's width each day. Moving a hive further than this calls for rather more preparation.

Moving a greater distance

The hive must be secured so that the bees cannot escape in transit. The entrance to the hive must be stopped up and secured in position and the various boxes of the hive should be stapled together, or the hive should be securely strapped. Do not rely on carpet tape or any other single method. You need to be doubly sure the hive will stay intact and together.

Hives are heavy, and you will need help to carry the hives on to your transport. Use a proper levered truck to carry the hives, and never use a wheelbarrow because they tip easily and are difficult to control when they are carrying a heavy weight.

If you are moving bees in the height of summer you can remove the crown board and put a mesh screen in place so that there is increased ventilation.



Above: *The clasp holds the strap in position – smear it with petroleum jelly to stop it rusting.*

Moving hives to and from various food sources is beyond the scope of the very new beekeeper, but bear in mind that once your colony has taken advantage of a food source, such as a field of oilseed rape or a heather moor, there will be a lot more bees in the hive than when you originally moved it. Retaining all of these bees might need the application of a fresh super full of foundation.

Moving bees in nucleus boxes

Perhaps the most convenient way of moving a single hive is to put the frames at dusk into nucleus boxes. These boxes normally have a deep, fitted lid, so there is no need to over-secure them. The rest of the hive can then be dismantled and transported safely.

Transport

When you move your hives by road the journey should be as smooth as possible. Plan your route in advance and leave plenty of time. Throwing the colonies around inside the hives can cause them to abscond when they get a chance to escape and, of course, you need to be sure that you do not damage the queen.

Above: *When moving your hive, ensure that you use straps to keep it secure.*

Pests and diseases

Bees are susceptible to an array of pests and diseases, but fortunately not all of them are devastating to the colony. Indeed, until the appearance of the varroa mite it was only acarine and foul brood, in its various forms, that were really deadly. Now a number of new problems beset honeybees.

Be aware that American foul brood, European foul brood and the pests, small hive beetle and tropilaelaps mite, are notifiable in most countries. This means that if you have, or suspect you have, any of these problems you must contact the appropriate inspector.

Hygiene

Most diseases get into hives because bees drift from one hive to another or because robbing bees and pests have entered a hive. It is also possible that beekeepers may introduce disease by failing to observe high standards of cleanliness when they are around and inspecting the hive. Hygiene is particularly important for people who regularly visit more than one site, perhaps members of an association or people who have apiaries in several places.

If you are dealing with more than one hive wear disposable gloves and change them between hives. Always make sure you disinfect your hive tool between hives. You can keep a solution of hypochlorite for this purpose. Make sure you always clear away debris from around the hive. Do not leave any cappings or end-of-frame cells that you remove around the hive, because they only invite robbing and other pests.

When you use old items in a hive – boxes, floors queen excluders and crown boards – everything that the bees can touch should be flamed with a blowtorch before use. Old wax should be rendered and the frames replaced. Plastic hives should be cleaned with hypochlorite.

Pests

Bees are much more susceptible to attacks from a range of pests during the winter months when they are not actively guarding the hive.

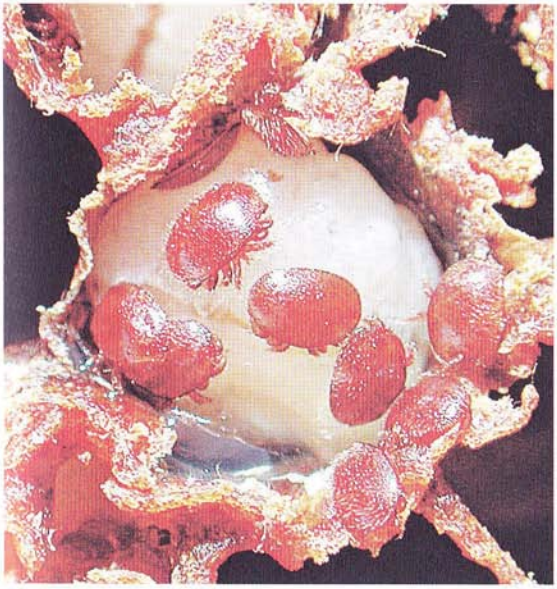
Some pests are more surprising. In winter woodpeckers are capable of making large holes in hives, but can be deterred by covering the hive with a wire mesh so that bees can fly in and out.

Robbing bees and wasps can be a problem, especially if you have recently fed the hive (see page 81).

Varroa

Varroosis is the most serious problem facing beekeepers. The mite *Varroa destructor* causes deformities in bees and will eventually lead to the collapse of the entire colony if it is untreated. The red, pill-shaped mites are just over a millimetre in diameter. It was originally a pest of the Asian honeybee, *Apis cerana*, and these populations seem to have built up some immunity. The Western honeybee, *Apis mellifera*, however, has none.

Although it is serious, varroa is not a notifiable disease because it is ubiquitous – everyone has it and every beekeeper has a responsibility to keep the problem under control. Infestations are now found all over the world, except Australia, and within a decade it has become an important apine pandemic. Sometimes a few thousand mites can be fatal to a colony, but in other hives only a few hundred mites can wipe out the bees.



Above: *Varroa mites sucking the life from a developing grub.*

Much depends on the overall health of the bees, and the presence of tracheal mites is also thought to be an important factor.

In an infected hive the brood emerge with deformities that make them useless to the colonies. Others die at the pupal stage in the brood itself and remain until the adults remove them. The beekeeper will notice a patchwork of dead brood, and if nothing is done the colony will be in danger of collapse.

The mites are spread over huge distances on the backs of bees, and hives are infected by the natural processes of swarming, and robbing. The adult female mites will enter a brood cell just before it is capped and will feed on the haemolymph of the immature bee. She will also lay eggs in the cell and the offspring mate in the cell. When the bee emerges from the cell the mites escape, although only adult females survive – immature mites and males are not viable.

The numbers of mites fall in winter – they are unable to grow in brood cells because the queen has usually stopped laying – but the remaining mites huddle with the bees in their winter ball and live off the haemolymph of adult bees.

Pyrethroid insecticide treatment

For several years a pyrethroid insecticide was used to control varroa, and beekeepers kept treated strips in the hive. It did not take long for the mites to become immune to insecticides, and this kind of treatment has been superseded. A thymol-based product is now used, and it works in such a way as to make it almost impossible for mites to become immune (see page 94).

The problems that pyrethroid resistance brought has led to the concept of managing bees through an integrated pest management system. The basis of the system is knowing how many pests you have in your hive and the likely outcomes of their presence at particular times of the year.

Developing an integrated system

You must first make a judgement about the health of your bees, how the colony is doing and how they are likely to do in the future. Then you can implement a couple of basic procedures to reduce the number of mites in the colony without having to resort to chemicals.

First, there is a lot of evidence that mites that fall off the frames alive are able to climb back into the brood box if they hit a solid floor. Therefore, if you put a mesh floor in the hive the mites are more likely to fall right out of the hive and find it impossible to get back into it. It is possible to account for up to 30 per cent of the varroa population in this way.

Second, the female mites prefer to feed in male, drone brood. You can encourage drone brood production by putting a super frame into the brood box. When the worker bees make hanging comb in this formation it is usually drone brood. By simply removing the brood when it is capped you will also remove a lot of mites.

The mite count

Clearly, given the ecology of the varroa mite, the numbers will increase in proportion to brood production, and from late spring the mite numbers will follow the activity of the hive. You need some way of working out when to intervene with harsher remedies.

The increase in mite numbers depends primarily on the population of mites at the beginning of the season. If there are 100 mites in the colony in spring you are likely to see over 1,000 by summer, and although it is difficult to be sure and exact in these circumstances, a hive population of 1,000 mites seems to be a critical level.

It is possible to estimate the number of mites in a colony either counting the number of dead mites falling from the frames through the mesh floor and on to a varroa floor beneath it or by looking at the number of capped brood cells that have mites inside them. Monitor your bees at least four times during the year: in early spring, after the spring honey flow, at harvest time and again in the autumn. The bee club will have a microscopist to help.

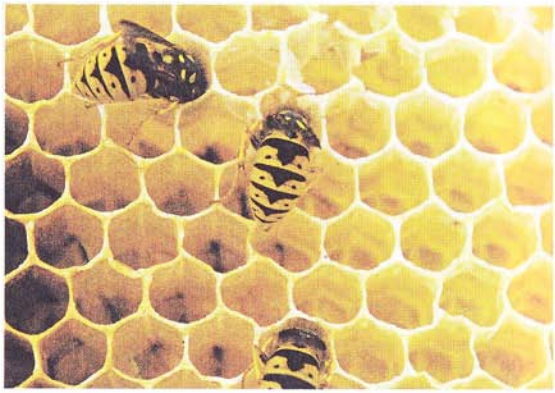
If you collect mites over a period of, say, five days you will be able to determine a daily mite fall rate. It has been estimated that a colony is in danger if the fall rates are around: 0.5 mites in early spring; 6 mites in late spring; 10 mites in early summer; 16 mites in midsummer; 33 mites in late summer; and 20 mites in early autumn.

The other method involves uncapping about 100 brood cells that are just about ready to come out. If you find that about 10 per cent of the cells contain varroa, the colony is in trouble.

Other treatments

Now that varroa mites have developed resistance to pyrethroid insecticides, other methods have to be used to minimize mite numbers. Beekeepers should take care that insecticide residues are not found in honey. Research into new treatments and special breeding programmes to create varroa-immune bees are under way.

The available pesticides still include some pyrethroid treatments, as well as aromatic products based on thymol. Follow the manufacturer's guidelines to the letter, especially as regards the timing of applications.



Above: *Wasps robbing honey from a frame.*

Another, non-approved treatment that is popular with many beekeepers uses oxalic acid, which is simply dribbled between the frames as a 3 per cent solution.

Mice

In summer, when the bees are active, mice will usually be deterred from entering the hive by the stings, but in winter, when the bees are not active, mice can be a real nuisance if they get into a hive, making their nests from grasses and leaves and chewing combs. Moreover, once a mouse is actually in the hive its offensive smell deters bees from attacking it. Keeping mice out in the first place is best, so fit a mouse guard, a piece of metal (usually zinc) with holes in it, over the entrance in late summer to early autumn and remove it in spring, when the bees are fully active. In winter, on the days when it is warm enough for bees to fly, they will be able to get through the holes in the mouse guard.

Wasps

In late summer and early autumn wasps often try to enter the hive to take honey. Keep them out of the hive by

reducing the size of the hive entrance – it is easier for the guard bees to protect a small entrance. Make sure that the outside of the hive fits perfectly together so that there are no small cracks through which a wasp can enter to rob the honey.

Wax moths

Two kinds of wax moth, the greater and lesser, are more of a problem to stored comb, which they eat, than to the bees themselves. The moths are rarely visible in summer when bees are active, and a healthy colony will often be able to expel any intruders. In autumn and winter, however, the moths tunnel into wax combs, especially brood comb, to lay eggs and produce silvery threads. The larvae of the greater wax moth also chew indentations in wood (both in the hive itself and in stored hive furniture) where they spin cocoons in preparation for pupating. The bees seem to leave them alone.

One of the easiest ways of treating stored frames is to put them in the freezer for 24 hours or so because the larvae are susceptible to cold. In the hive you will have to use a proprietary product.

Diseases

The most important disease facing bees is varroosis, the disease caused by the varroa mite, which is discussed earlier, but there are several other diseases that can be troublesome.

Foul brood

Both types of foul brood, American and European, are notifiable diseases. They are caused by bacteria. American foul brood (AFB) causes infected bee larvae to die in the cells, while European foul brood (EFB) tends to affect unsealed brood. There is no known treatment for AFB, and both the hive and its contents must be destroyed if the disease is discovered. Minor outbreaks of EFB can sometimes be overcome by shaking the colony into a new hive, but if this is ineffective, again, the hive and contents must be destroyed.

Above: *The stringy form associated with foul brood.*

Nosema

A disease of the bees' digestive systems, nosema is caused by a protozoan. The bees suffer from dysentery, and the infection is spread when workers in the hive try to clean up the mess by licking it. Nosema weakens bees, preventing them from functioning as normal, but it is rarely fatal. Infected bees can be treated with antibiotics given in sugar syrup in autumn. Avoid infection by maintaining scrupulous hygiene in and around your hive and by thoroughly cleaning all stored hive furniture and by fumigating empty hives.

Acarine

The disease is caused by a mite, and it affects the bees' trachea (breathing tubes). Although it is not fatal, bees are weakened and severe infestations of the mite can lead to the collapse of the entire colony. There is no known treatment, but a proprietary menthol gel has been shown to have some effect. Some bee hybrids seem to be more susceptible than others.

Honey and other products

Many people develop an interest in beekeeping because they want to enjoy the honey that is harvested in late summer, and from a well-managed hive it is possible to get up to one hundred jars. Honey can be used in dozens of recipes, some of which are given on pages 124–35, and in mead. Bees also produce wax, which can be turned into candle or polish, and propolis is also collected.

Honey

For thousands of years the goal of our relationship with bees has been to remove the honey from the hive. A well-managed hive can produce far in excess of the bees' requirements, leaving the beekeeper free to harvest it.

Harvesting honey

Remember that when you harvest honey you should replace it with an equivalent quantity of sugar syrup. A careful beekeeper will not take more than the colony can easily afford to miss. Putting the bees in danger for a few frames of honey after a cold, wet summer is counterproductive.

The honey you take will be probably be in the topmost supers, and you should leave one full super for the bee's winter store. You can remove one super to make room for a feeder, set on a crown board (see page 82), and this will allow you to top up the syrup quickly and without chilling the bees on cool autumn days.

Expelling the bees

To get the honey from a super you need to find a way of removing the bees. If you set the super on the crown board with bee escape valves in the holes, the bees can go down into the colony but not return. Put the roof on and wait for at least a day before opening the hive again. Do not wait around when taking honey.

Remove the roof and take the super well away from the hive. Remember to take out the bee escape valves and set the feeder in place over the holes in the crown board. Put the roof back on. This method has minimal impact on the bees.

There will still be a few bees on the frames, so remove them carefully so that they can return to the hive. Putting the frames inside a sealable plastic box will allow you to remove the honey from the hive area.

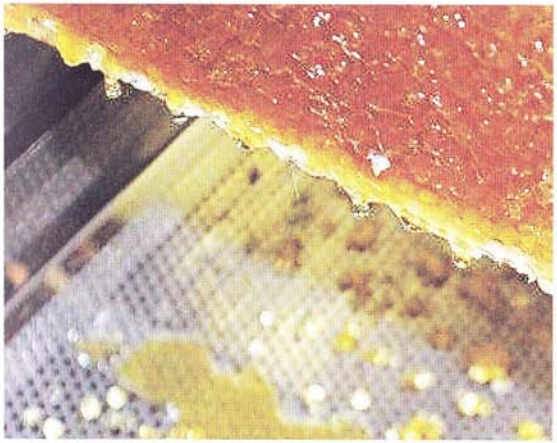
Above: *Using a hot, sharp knife remove the wax cappings, using the frame as a guide.*

Getting honey from a frame

Removing honey is a complicated business: you have to remove the cappings, extract the honey and finally transfer it to jars to store it. You will need honey knives, extractors, filters and sterile jars all ready and available at the right time and in the right place. If you can, extract your honey at your local beekeepers' club or association, but if you cannot, make sure that all the surfaces and equipment are sterile and that you can work without being disturbed. Close the doors and window so that bees or, worse, wasps aren't attracted to the honey and make a nuisance of themselves.

Moving supers

A super full of honey is surprisingly heavy, and if you have more than one to carry you should use a trolley. Always use both hands to collect and move honey, and make sure that when you lift you do not strain your back. If you find it difficult to move heavy weights, ask someone to help you.



Above: *Decapped honeycomb dripping on to a tray.*

The jars used to store and sell your honey are often traditional, and most hold the metric equivalent of 1 lb (455 g). Be wary of using washed jars from last year, particularly if they have been used for anything else. Honey absorbs flavours and smells very easily, often making them more intense. Pickle vinegar is probably the worst offender. You must use sealable jars because honey is hygroscopic – it will draw water from the atmosphere – and this can lead to fermentation and consequent spoiling. You can usually buy special honey jars quite cheaply from your local bee club or beekeeping stockist.

Removing the cappings

Use a capping knife – an electrically heated knife that slices through the wax – to open the cells. Stand the frame on its side in a container in which you can collect the cappings, then cut away the capping on both sides of the frame (the honey will start to dribble out) and put the frame into the extractor.

If you do not have a heated capping knife you can buy a comb decapper, which resembles an ordinary hair comb but has angled metal splines. You can also use a serrated kitchen knife, heating it in a container of boiling water. Make sure that the container you use for the hot water is completely free from taint and residues. Save the cappings: they have honey on them and the wax is valuable and can be processed later (see pages 104–5).

Extracting honey

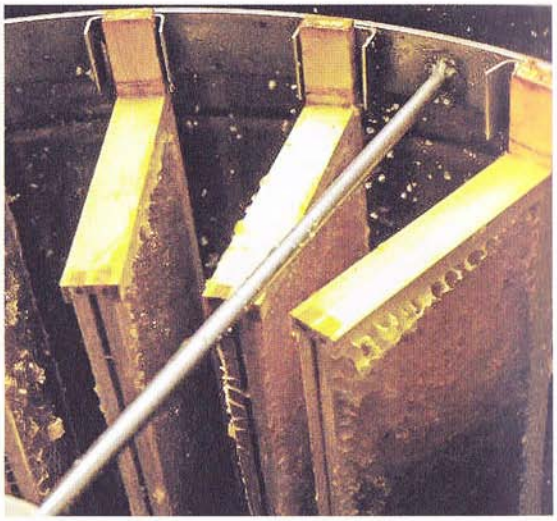
If you do not have an extractor, rest the frame over a large, sterile, taint-free, food-grade container or bucket. Gravity will cause the honey to dribble from the decapped combs and into the bucket. This takes ages to complete and you will never get all the honey out of the comb, so it is worth using an extractor.

Honey extractors rely on centrifugal force to remove the honey from the frames. The frames are inserted into a drum, which spins, slowly at first, so that the honey is thrown out of the cells on to the inner casing of the drum, from where it falls into the reservoir below. You might have to repeat the spinning process after moving the frames around to make sure you get all the honey from both sides of the frame.

A tap at the bottom of the reservoir has a coarse filter to remove any large pieces of wax. From here the honey is transferred to a holding vessel for 24 hours to allow the bubbles to rise to the surface. A second filtering gives especially clear honey.

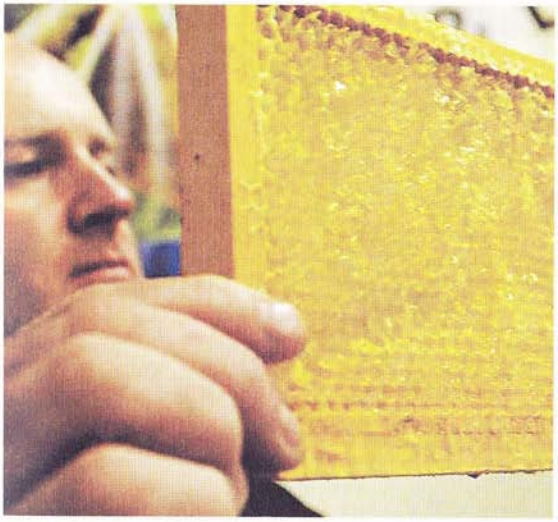
Leaving the honey in the settling vessel so that air bubbles can rise to the surface does mean that the honey will have cooled, and this will make second filtering and pouring into jars difficult.

1 Use a comb or a knife to decap the cells in the honey frames. The decapping comb is more efficient.

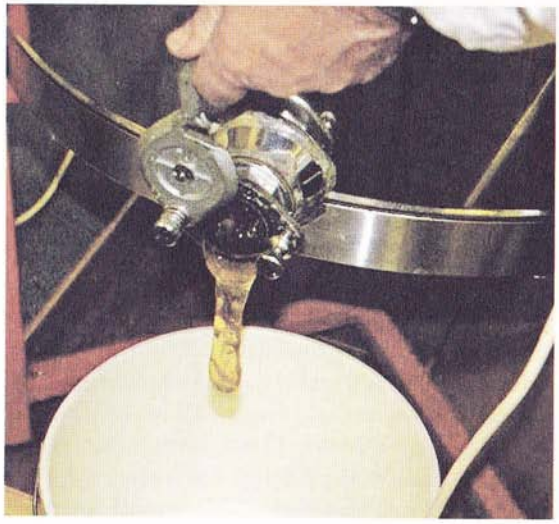


2 Load the extractor so all the spaces are filled. Make sure the drum is evenly balanced.

3 When the extractor is full, start the motor (or turn the handle) slowly so it does not shake, and gradually increase the speed to maximum. The extraction process can take 10–20 minutes, and then you should check both sides of a frame for residual honey.



4 Replace the frames, once extracted, into the super box and put this back on the hive for the bees to reclaim the last droplets of honey for their own stores.



5 Once the honey has rested to remove the air bubbles you can pour it off into a food-grade bucket or honey jars. This takes a long time and can be quite sticky.

6 The decappings will be full of honey. Store them in a colander or a warm gravity extractor to get the last drops of honey from them and finally use the remaining wax by washing it thoroughly in plenty of water to remove any remaining sweetness.

Types of honey

Whether the honey is runny (clear) or set honey depends on where the bees have collected their nectar.

Set honey usually depends on the crystal size, and honey collected by bees that have visited oilseed rape sets very hard. All set honey can, of course, be melted by gentle heating. Do this in a water bath or bain marie so that the combs are not subjected to direct heat. If you are able to remove the frames from the hive as a soon as they are full the honey will not granulate immediately and will consequently be easier to extract. However, all honey granulates after a time, a phenomenon caused by the relative concentrations of glucose and fructose.

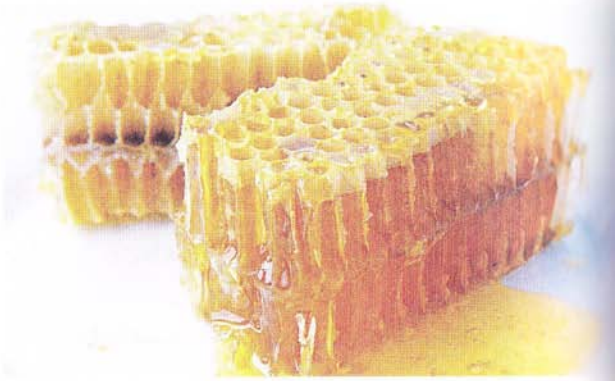
It is possible to blend honeys from various sources to create a range of flavours, but the actual nutritional value of the honey will be unaltered. Honeys from single plants generally have interesting fragrances and flavours, but when you consider how far bees will have travelled to forage, you can see that your hives would have to be set in a huge area devoted to a single plant – such as a heather moor – to give a single floral honey. For the same reason it is difficult to obtain truly organic honey.

Dark honey

Heather is a dark, richly flavoured honey, which is gathered from moorland in late summer. Heather honey is somewhat gelatinous and will not come out of the cells under normal extraction methods. The combs are removed and pressed in muslin cloths so that the honey is forced out of the comb under pressure.

Cut comb honey

Cut comb honey is created either with unwired foundation or in a top-bar hive, where the bees create all the comb without the aid of foundation.



Above: *Comb honey is delicious and attracts a premium in the shops.*

The comb is not uncapped, and the honey remains sealed and in pristine condition. This honey attracts a premium price among those who like it. If you have a top-bar hive you can simply cut the honeycomb.

Selling honey

If you are simply selling a few pots of honey to friends and family you can usually do so quite freely. However, you must be aware of the legislation and regulations governing food production, farming and labelling, and you must make sure that your honey meets specified standards if you plan to sell a significant amount.

Propolis

Also known as bee glue, propolis is a mixture of various resins and wax gathered by the worker bees from plants.

Propolis in the hive

This substance is filled with terpene and other aromatic chemicals, and it is used by bees within the hive.

Its main function is to 'glue up' the hive, which improves its structural integrity, but bees also use it to propolize almost anything that takes their fancy, which can be irritating for the beekeeper but is useful to the bees (see page 33). It used to be believed that it was used to reduce draughts by filling all cracks and gaps, but this theory has been questioned in recent years as research has shown that bees benefit from being in a well-ventilated hive. Nevertheless, most beekeepers will leave propolis in place in winter. It is also reduces vibrations in the hive and makes the hive easier to defend by narrowing gaps.

Propolis is also used as an external antiseptic. It fights infection in the hive remarkably well, and this has led to the idea that it can be used in human medicine.

Propolis and humans

Chinese and homeopathic medicines use propolis to treat burns, ulcers, allergies and infections, and although much of the evidence is anecdotal, there is some evidence that it can be successful.

It has been used to treat viral infections, particularly sore throats, and to this end is made into a tincture. When propolis is dry it hardens almost like rock, and many beekeepers pass a small lump around their mouths as a guard against colds. They say it works, although a proper scientific investigation into these claims has yet to be undertaken. Chemical analysis has revealed that propolis is high in antioxidants and that it has anti-fungal and some anti-viral properties, but scientific tests have not yet confirmed these findings in humans.

It is deeply coloured, and if you use propolis it will stain anything it comes into contact with and will resist any attempt to wash out. It is said to have been used for many hundreds of years as a colouring for musical instruments.

You can buy or make your own propolis dissolved in alcohol, when some of its efficacy is said to be removed. Although it is harder to dissolve, propolis in water retains most of its active ingredients. It is not likely that you will be able to sell your propolis for medical reasons, but you can use it yourself.

Below: *Propolis looks unappetizing, but is used because of its health promoting properties.*

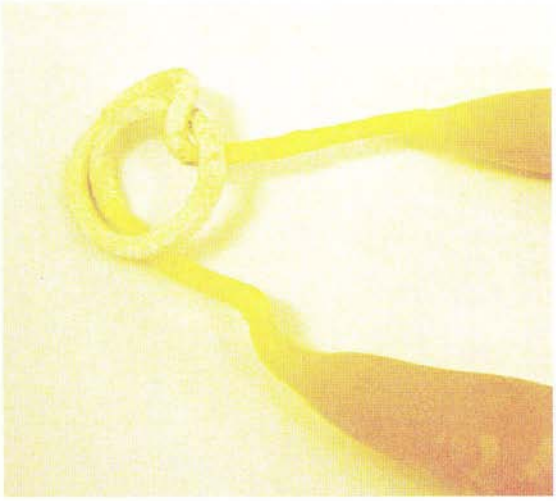
Beeswax

Beeswax is a remarkable substance that is produced by a series of glands on the underside of worker bees and is then manipulated by the various house bees to create the amazing architecture of the hive.

Using beeswax

The production of beeswax was once a major industry, particularly for the making of candles and polish. Beeswax candles, in fact, remain one of the only truly carbon-neutral sources of light because all the carbon dioxide given off by the candle has been taken from the atmosphere by the plants that made the bee food.

When you are extracting honey (see pages 98–101) the excess honey that is attached to cappings and comb can be extracted further by wrapping them in muslin and allowing them to drain. From there they can be soaked in boiled, cool water to dissolve the honey (this liquid can then be used to make mead, see page 134). The wax can be allowed to dry and prepared for use.



Left: *A set of home-made beeswax candles.*

Melting wax

Do not overheat wax. The best method is to use a heatproof dish set over hot water – in the same way you would melt chocolate – or a double saucepan or bain marie. Do not boil wax, because it can flame.

One method is to put the wax in a muslin bag and immerse this in water. Gently heat the water to about 62°C (144°F), when the wax will melt and rise to the surface of the pan.

Alternatively, you can use a solar extractor, which is a glass frame that is orientated towards the sun, until the temperature reaches 60°C (140°F). The container is made of metal and has a window through which the sunlight enters. Put the wax on a plate set at an angle of 45 degrees. Sometimes the plate rests on metal to increase the heat retention in the extractor. As the wax melts it flows on to a collecting plate on the floor. You can use this wax to make new foundation or sell it, and some companies will allow you to barter wax for foundation.

You can also make the wax into candles, which is more difficult than it might seem because you have to make sure that the wick goes down the centre. You can buy moulds to make professional-looking candles.

Beeswax products

Before using beeswax cosmetics on the sensitive skin of your face and neck, always check that they are safe by testing them on your hands.

There are lots of recipes available so that you can make your own soap, lip balm, make-up remover and a host of other products. By way of illustration this hand cream recipe is excellent for those working outside and the lip balm is the richest you will ever find.

Basic hand cream

This could hardly be easier to make. In a double boiler melt together equal amounts of beeswax, cocoa butter and almond oil. Stir thoroughly to combine, and then pour the mixture into a mould. If you wish you can add a few drops of essential oil.

These make delightful gifts. For instance, if you add a few drops of lavender essential oil you could decorate the bar with a sprig of lavender flowers added to the mould. The cream smells wonderful and is antiseptic.

Lip balm

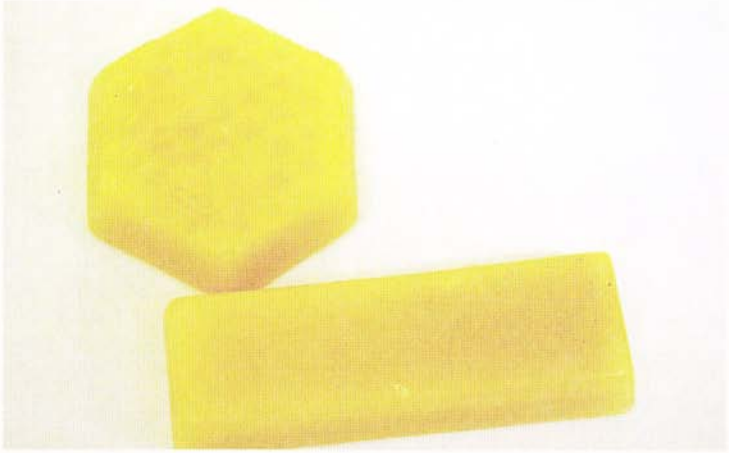
Mix together 100 g (3½ oz) coconut oil (or almond oil or a mixture of the two) and 60 g (2½ oz) beeswax. Melt gently in a double boiler and blend thoroughly, then transfer to a small pot for ease of use.

You can add all sorts of things to this basic recipe, including a vitamin E tablet and a drop of essential oil (try peppermint or rosemary), or you could change the oils and use light essential oils or shea butter instead.

Furniture polish

This wonderful substance is simply a mixture of two parts pure turpentine to one part beeswax. You have to be very careful when you're making it to avoid fire. Always wear gloves and observe proper fire precautions.

Carefully heat 500 g (1 lb) wax in a tin set above a saucepan of water. Make sure that you keep the turpentine well away from the heat source. When the wax is completely melted turn off the heat and take it away to a separate place, far removed from any flame. Pour it into a large tin with 1 litre (1¾ pints) pure turpentine and stir well to combine thoroughly. Pour the warm mixture into moulds and when it has set keep it in a dry, cold place. The mixture is flammable, so always handle it with care, but it is the very best polish.



Right: *Beeswax can be used to make a variety of cosmetic and household products, from lip balm to furniture polish.*

The bee garden

The sound of bees as they buzz from flower to flower gathering pollen is one of the pleasures of the summer garden. However, beekeepers will be anxious to ensure that there are sources of food for their bees from early spring through to autumn, whether this involves siting the hives near to suitable plants or providing as wide a range of plants as possible in their own gardens.

Bees and biodiversity

Botanists have long studied the rise of flowering plants (angiosperms) but have not always appreciated the remarkable part that bees have played in this story.

Bees and pollination

The honeybee and its cousin, the bumblebee, are ideally adapted to the job of pollination and are by far the most important pollinators and consumers of nectar. Even if there were no humans, honeybees would still be servicing the huge range of plants and flowers that cover the earth. Bees and plants exist only for their own purposes, and it has to be said that humans represent the greatest threat to bees, largely from pollution.

Most pests and diseases have evolved without the aim of eradicating their host, yet humans have endangered bees around the world, partly through the destruction of their natural habitats, partly through pollution and partly by moving bees from country to country so that new diseases and problems arise so quickly that the bee has little time to find its own solutions and defences.

In the garden, what is good for the bees is also good for other insects – butterflies, moths, hoverflies and even wasps – and every living creature has a place in the complex ecosystem that exists in every back garden. These days most gardens contain conglomerations of plants from all over the world that would never have grown together in the wild, and it is up to the gardener to make this work to the benefit of the insects.

Left: *Bees have evolved to draw nectar and pollen from flowers and nothing else.*

Bumblebee nest box

Bumblebees are very efficient pollinators and are worthy of encouragement to the garden, particularly as they often struggle to find natural nesting sites. To help the population flourish, try making a homemade bumblebee nest box in the early spring.

Take two plastic flowerpots, line with moss and secure the open ends together with watertight sticky tape. Site the box in a sheltered spot – under a hedge is ideal – by burying one end in the ground with the drain holes above the surface, through which the bees will enter. Alternatively, position the nest box under a shed.

Right: *Make your apiary as beautiful as possible; more flowers mean more honey.*

110 Gardening for bees

There are few things more enjoyable for the beekeeper than being able to watch his own bees foraging in his own garden and then enjoying a crop that other people will miss: the millions of droplets of nectar, condensed and preserved and converted into wonderful honey, full of the goodness of the garden.

Above: *The aroma of plants and flowers is very important to foraging bees.*

Choosing plants

In the garden, as in nature, plants respond to being pollinated by bees and go to extraordinary lengths to avoid passing their own pollen to their sex cells. It is known that the yield from crops is improved by 30 per cent if bees are available for garden pollination.

The major sources of pollen and nectar include fruit trees, especially *Malus* (apple) and *Prunus* (cherry), *Salix* spp. (willow), *Tilia* spp. (lime) and *Trifolium* spp. (clover). Bees also visit *Brassica napus* (oilseed rape) and *Erica* , *Calluna* and *Daboecia* spp. (heather, ling). As well as these, your garden can include a wealth of other pollen-rich plants, from *Lavandula* (lavender) and *Buddleja* (buddleia) to roses and *Lonicera* spp. (honeysuckle). There should be flowers in every month.

Take the time to cultivate your plants as naturally as possible, and this includes your choice of species and cultivars. Modern plants have been hybridized and bred for their colour, habit of growth, keeping qualities and disease resistance, and it is usually the older, traditional varieties and cultivars that are richer in pollen and nectar. Also try growing a packet of wildflower seeds.

Beekeepers will avoid growing double-blooming flowers, which produce much less nectar than single-blooming types. It is also more difficult for the bees to get to the nectar and pollen of flowers that have multiple petals, which can actually exclude bees and other pollinating insects. Also avoid F1 hybrid plants, many of which have impaired pollen production because they have been hybridized so that they will not set seed.

Techniques

Needless to say, you should practise organic gardening, avoiding the use of all insecticides and sprays and allowing your garden to develop a natural balance of pests and predators.

Above: *Medicinal plants, like this lavender, do pass on some of their flavour and properties to the honey.*

One useful technique that is often overlooked is deadheading. Regularly removing pollinated flowers cuts off the hormone supply of the ripening seeds in the fruit or seedhead. These hormones suppress flower production, and if you deadhead you are more likely to get extra blooms on each plant and, consequently, more food for your bees.

Get into the habit of feeding your plants with good-quality, well-rotted compost. Not only will regular applications improve the soil quality and structure (giving healthier plants), but the phosphates and nitrates it contains will encourage your plants to produce better quality pollen and nectar. Pollen in particular needs nitrogenous excess, and the more there is available to the plant the more nutritious the pollen becomes.

Keep your plants well watered so that they do not suffer from water stress. Wilting plants shut down photosynthesis, and this will be reflected in nectar flow. If possible, use collected rainwater and always water at the roots rather than the leaves.

Remember that by surrounding your garden with high walls, hedges or fences your bees will be forced to fly high and will not bother the neighbours.

Best plants for early nectar

In addition to the ornamental plants noted here, fruit trees, such as *Malus* (apple), *Prunus* (cherry) and *Pyrus* (pear), produce blossom in early spring and depend on early-flying insects, including bees, to pollinate them. If you have space, a couple of flowering cherries will keep the hive busy for a week.

- *Anemone nemorosa* (wood anemone)
- *Aubrieta* (aubretia)
- *Aurinia saxatalis* (gold dust, yellow alyssum)
- *Cyclamen coum* (cyclamen)
- *Eranthis hyemalis* (winter aconite)
- *Galanthus nivalis* (snowdrop)
- *Hyacinthoides non-scripta* (bluebell)
- *Muscari botryoides* (grape hyacinth)
- *Primula veris* (cowslip) and *P. vulgaris* (primrose)
- *Ribes sanguineum* (flowering currant)
- *Viola odorata* (garden violet, sweet violet)

Best plants for late nectar

All the plants listed here will flower from midsummer and, depending on the weather, into autumn. Deadhead regularly to encourage the plants to produce new blooms.

- *Aster* spp. and cvs. (aster, Michaelmas daisy)
- *Calendula* spp. (pot marigold, English marigold)
- *Centranthus ruber* (red valerian)
- *Echinacea purpurea* (coneflower)
- *Hedera helix* (ivy)
- *Helianthus annuus* (sunflower)
- *Lonicera* spp. and cvs. (honeysuckle)
- *Sedum spectabile* (ice plant)
- *Solidago* cvs. (golden rod)
- *Tagetes* cvs. (marigold)

Above: *You can increase the production of new flowers by deadheading old ones.*

Planting

With some planning and forethought it is possible to have flowers available at most times of the year when bees are flying, from early spring to late autumn.

The salvation of many bee colonies, because of the huge amounts of pollen it produces, is the plant *Impatiens glandulifera* (Himalayan balsam), a tall annual, bearing white, pinkish or red flowers from midsummer to early autumn. It is however, invasive, explosively spraying seed for metres around each parent plant, and in some areas, where it has escaped from gardens into the wild, it is regarded as a pest and must be uprooted wherever it is found. Beekeepers, however, are delighted when they see their worker bees landing on the alighting board covered in pollen as though they have just escaped from a box of caster sugar.

Other plants that used to be called weeds have become accepted in the garden. Buddleias, named after the Rev. Buddle, still found growing wild on rubble and other inhospitable places, have found a new niche as the butterfly bush. They are equally palatable to bees, however, and cultivated varieties, in shades of white, blue and purple, are just as useful as the species. Other plants, such as fragrant *Lonicera* (honeysuckle), are among the best providers of energy for your bees.

Plants for honey flow

Early spring
- *Alnus* spp. (alder)
- *Populus* spp. (poplar)
- *Prunus avium* (wild cherry) and *P. spinosa* (blackthorn, sloe)
- *Salix* spp. (willow)

Mid-spring
- *Malus* spp. and cvs. (apple)
- *Prunus* spp. and cvs. (cherry, plum, etc.)
- *Pyrus* spp. and cvs. (pear)
- *Taraxacum officinale* (dandelion)

Late spring
- *Aesculus hippocastanum* (horse chestnut)
- *Crataegus* spp. (hawthorn)
- *Rubus idaeus* and similar (raspberry, etc.)

Early summer
- *Brassica napus* (oilseed rape)
- *Tilia* spp. (lime)
- *Trifolium* spp. (clover)

Midsummer
- *Filipendula ulmaria* (meadowsweet)
- *Lupinus* spp. and cvs. (lupin)
- *Rubus ulmifolius* (blackberry, brambles)

Late summer to early autumn
- *Calluna, Daboecia* and *Erica* spp. (heather, ling)

Useful midseason plants

Perhaps surprisingly, midsummer is often a time when flowering plants are in short supply. After the burst of spring-flowering bulbs and shrubs there is often a lull, and beekeepers need to plan their planting carefully so that there is a constant supply of nectar and pollen.

Although they are widely regarded as a weed and are dug out and cut back in most gardens, *Rubus*

ulmifolius (brambles) are a great source of nectar for the bees. They are in flower from early summer and are never free of bees.

Lavandula (lavender) produces huge amounts of nectar throughout the summer, especially when there is plenty of nitrogenous material in the soil.

There are several types of spiraea, medium-sized shrubs that bear milky pink and white flowers. They are all prolific pollen producers full of nectar, so it is not unusual to find bees on the flowers all day long.

Buddleias can be cut back hard in early spring, delaying the flowering until mid- to late summer. Cut back the stems to about 45 cm (18 inches) high, and it will grow to about 2 metres (6 feet) high and produce a mass of nectar-rich flowers. If you have more than one buddleia, prune them at different times so that you have flowers from early summer to mid-autumn.

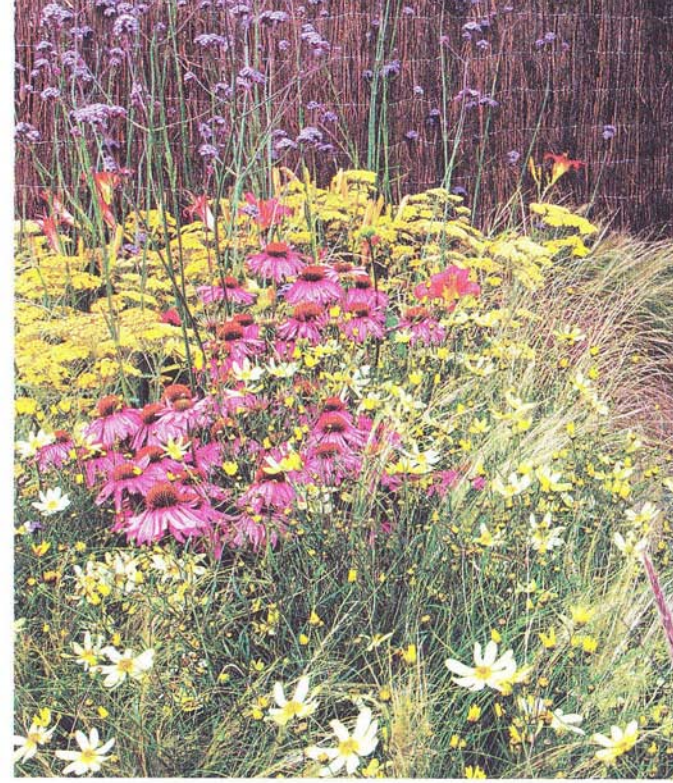
Flowering onions, *Allium* spp. and cvs., produce masses of nectar and are also interesting to look at. They bloom from early summer onwards, and you will see bees clustering around the flowerheads. The flowers of the related *Allium schoenoprasum* (the herb chives) are also rich in nectar as well as being useful in the kitchen. These plants are a valuable source of the chemical sulphonamide for the colony, because they are highly antibiotic and important for the health of the hive.

All the labiates (nettles, dead nettles, vetches, peas, beans, lupins and so on) seem to have evolved with bees in mind. Some of the flowers can only be accessed by bees, and the blooms are a useful source of good-quality nectar and pollen.

The wildlife garden

Ideally, every garden should have an area that is set aside for wildlife, but that is not always possible in a small garden.

However, if you have room for a section of your garden to be devoted to wild plants, this will be a tremendous boost for your bees, because most produce fantastic amounts of pollen and nectar.



Above: *Create a feast for bees consisting of as many different flower types as possible.*

One of the bees' favourite wildflowers is the pink-flowered *Chamerion angustifolium* (rosebay willow herb), which is especially rich in pollen. *Convolvulus* spp. (bindweed), which can be such a pest in the tidy garden, is also a great producer of pollen, as is *Taraxacum officinale* (dandelion) in spring. Different species of *Trifolium* (clover), now banished from lawns, were once a major food for bees and were widely grown as a green manure.

Many herbs are attractive to bees, and a wildlife garden is a great place to grow *Melissa officinalis* (lemon balm), whose Latin name suggests that it is the official bee plant. It is also known as bee balm and will grow well in most reasonably well-drained soils, but take care because, like *Mentha* (mint), it can be invasive.

The beekeeping calendar

Your beekeeping year will largely depend on whereabouts you live and, of course, on the weather. A cold snap early in the year may find your bees starving and freezing into mid-spring, even if you live in a temperate area, and wet summers might make them languish as they try to avoid driving rain. In short, there is no such thing as a typical beekeeper's year, and as you gain experience you will be able to judge for yourself which actions will be necessary under various circumstances. The following are, therefore, guidelines only of the actions that you need to take, month by month, to keep your bees healthy and productive.

Spring

Spring is the time when the bees burst into life and get busy in the hive. It is an exciting period for the beekeeper as he must play cat and mouse with the weather, while hoping for a good crop of honey from his hive.

Early spring

The beekeeper's year begins in spring when the first flows of honey and pollen are matched by an increase in bee activity. The queen should be starting to lay eggs now, and the workers that overwintered should be beginning to forage. There will, however, still be plenty of cold days, and you should resist the temptation to open the hive, even if the bees seem to be flying happily.

Heft the hive to estimate how much food there is. Consider giving the bees a feed of syrup. If your feeder is on top of the crown board you can feed without letting any chill air into the hive, but avoid doing this on a dank, cold day. In a very cold spring you might need to think about feeding pollen or a pollen substitute.

Bees will fly on warm days, visiting apple blossom and storing pollen and honey. The numbers of bees will be gradually increasing because the queen will be laying. It is hoped that there are enough foraging bees and honey reserves to match the increasing burden of the new young.

- Check for signs of damage at the entrance to the hive and repair as necessary
- Change the floor of the hive, which will allow you to remove any rubbish and detritus and also to check for the presence of varroa mites
- If you find any signs of varroa infestation apply an appropriate treatment, for which you can get help from your local bee club or inspector

Above: *The first tentative inspection of spring. Choose a warm day and open the hive just for a short time.*

- Even though fruit trees should be coming into bloom check the weather regularly because the bees will stay inside in a cold snap and may need extra food
- Give a feed of syrup if necessary or of pollen or pollen substitute in very cold weather

Mid-spring

Wait for a warm day to have a proper inspection of the hive, but do not linger inside because the weather can change quickly. The purpose of this first inspection is to check for the queen and any signs of disease as well as to see how much food there is.

- Take the opportunity of a warm day to inspect the hive and remove any obvious rubbish, such as bits of comb
- Look at the honeycomb and replace any that has become dark with age
- Clean all your spare wooden frames so that they are ready to be reused
- Remove the mouse guard
- Check the queen excluder, making sure that the holes have not been filled with propolis

Late spring

The colony should be growing quickly by now and may well need extra feeding, so make sure that there is plenty of syrup available. If your hive is near to plenty of tree fruits or even an orchard be ready to add an extra super.

If you have not already done so, change the floor if you are not using an open mesh floor and flame the solid replacement before putting it in the hive to kill any over-wintering pests and diseases.

Because swarms can happen at any time from now on consider having an extra 'bait' hive available. This is also the time to think about the age and health of the queen and to decide whether you will re-queen the hive.

- Begin your regular weekly inspection of the hive
- Add a queen excluder and a super with fresh foundation
- Remove any mouse guards that are still in place
- Initiate your varroa treatment regime if you have not already done so
- Check the queen's health and take account of her age in deciding what to do about queen cells
- Be alert to the possibility of swarming

Above: *Clean old boxes with a flame from a blowtorch to remove the wax and kill disease.*

Checklist

- Look for the queen – is she healthy, laying well?
- Check the food stores – do you need to feed?
- Replace empty frames
- Check for varroa and treat as necessary
- Check for signs of swarming in late spring
- Only inspect the hive on warm days

Summer

Summer is the season with the most production in the apiary. The quantity of bees will have swelled, and they will be filling the hive with nectar they will never eat. Make sure you are ready with lots of frames to cater for the excess honey.

Early summer

This is the time to replace the central frames by moving them from the centre of the brood box to the outside of the box. In a laying cycle of 21–22 days these will have emptied and can then be completely replaced with new frames. You can reuse these frames once they have been thoroughly cleansed, preferably by freezing, or you can harvest the wax and make new foundation or candles or any of the other beeswax products.

A healthy queen should be at her peak of laying, and you should see busy workers tending eggs and grubs and plenty of capped brood. Make sure there is plenty of brood space available and consider adding another brood box. Make sure that you have some spare supers, and remember to be alert to the possibility of swarming. Depending on the age of your queen you might consider artificial swarming, queen replacement or simply removing queen cells.

- Place an extra super of foundation in the hive if you think the bees may need more room
- Check the brood box, which should be almost full of brood by now, to see if you can take some honey off
- Make sure you replace any frames or supers of honey you remove
- Check on the queen every week
- Be vigilant about swarming
- If your bees have been on or near oilseed rape remove the honey before it granulates on the comb
- Check regularly for varroa

Left: *A common sight in summer, foraging bees vacuuming the nectar from every flower in the garden.*

Midsummer

In most areas the threat of swarming should have passed by now, but you should remain vigilant. You can add an extra super for honey – which you will steal later.

- Check regularly for signs of varroa mite infestation
- Check the health of the queen, especially if she is two years old, when you might have to consider replacing her by supersedure
- Add extra supers as necessary but make sure that the bees are capping the cells in the lower super
- Prepare to extract the honey and make sure you have plenty of jars ready to keep it in

Late summer

This is the time of year when you can harvest the honey. Remove the supers so that you can begin to extract the honey, but make sure that you leave the colony with at least 15 kilograms (34 lb) of honey for their own supplies or you will have to feed them.

- Remove supers so that you can begin to harvest the honey
- Make sure that you feed your bees to compensate for the honey you have taken
- Remove wax and render it together with the wax you already have
- Clean and replace dirty frames
- Close the entrance to the hive to a strip about 5 cm (2 inches) or less wide so that the bees can withstand wasp intrusion
- If you can, move the hives to heather moorland

Checklist

- Check the queen is laying well – look for patch brood
- Check for varroa and treat as necessary
- Make sure there are plenty of frames to take lots of brood and honey
- If the weather is unseasonably cool for a prolonged period consider feeding
- Buy honey jars and prepare the extraction equipment

Left: *Make sure the extractor is serviced and cleaned, in a short while it will be needed.*

Autumn

Autumn is the time when you help the bees prepare for the winter. Hopefully, you should now have your honey, and so you need to make sure the bees are healthy enough to get through the winter.

Early autumn

As the temperature begins to fall and day lengths shorten you can start to limit your hive inspections to once a fortnight. You will have to start feeding any colonies that need it, and you should expect to notice a decrease in the number of bees in the brood. Feed the bees before the weather turns cold so that they have the opportunity to take it down and evaporate it into honey.

- Remove supers from the hive, clean and dry them thoroughly and store them safely for next year
- Combine colonies if necessary
- Test and treat for varroa when the honey has been removed
- Begin to offer a feed of sugar syrup
- Fit a mouse guard over the entrance
- Keep an eye out for wasps and robber bees

Mid-autumn

This is the time of year when wax moths can be troublesome in the hive. The larvae scoop out indentations in the wood of the frames or sides of the hive, where they spin a cocoon before pupating. They then move into the combs, and the moths lay eggs among the brood.

- Keep an eye out for infestations of wax moths
- Before closing the hive for winter give it one final, thorough inspection
- Make sure that all parts of the hive fit snugly together to keep out draughts so that the bees do not have to expend energy in filling gaps with propolis
- Fit a mouse guard if you have not already done so

Late autumn

By this stage of the year you will have stopped feeding the bees altogether. Now is the time to make sure that your hives are secure and can withstand the worst of any winter weather. If you live in a windy, exposed area you should consider adding a weight to the top of the hive to prevent it from being blown over.

- Try not to disturb your bees
- Add some insulation to the top of the hive in the form of a piece of carpet or a purpose-made 'quilt'
- Use a strap to make sure that the hive is securely held together to protect it from both vandals and bad winter weather

Above: *Look out for wasps who may try to infiltrate the hive on their search for honey.*

Checklist

- Are there enough food supplies – do you need to feed?
- Decrease the entrance to a small gap to deter mice
- Clean away old drones ejected from the hive
- Do not inspect as frequently and allow the bees to glue up the hive
- Make sure the hive is protected from bad weather

Left: *Anti varroa strips placed between the frames of a brood box.*

Winter

In winter the hive is asleep, the bees huddle together in their brood chamber and have glued themselves a warm space where draughts are kept to a minimum. But there is plenty for the beekeeper to do.

Above: *Give your equipment a good clean with soap and water as well as disinfectant.*

Early winter

Now is the time to catch up on all your records and to make sure that everything is brought up to date, especially if you have been applying varroa treatments. Take the opportunity to read and study, and inspect the outside of the hive only, but keep a watch for a build-up of dead bees and leaves at the entrance.

Winter is an excellent time to clean out and maintain your equipment. Make yourself a customized utility box and build your frames of foundation for next year.

- Check the hive regularly for storm damage
- Check the hive for signs of damage by woodpeckers
- If you have not already done so, strap and weigh down the colony so that it cannot be easily kicked over by vandals or animals or blown over by strong prevailing winds

Midwinter

Even though the weather may make you want to stay indoors, remember to check the outside of your hive regularly to make sure that it has not been damaged by falling branches or tiles. Bees will fly on warm days in winter, and if there is snow on the ground they may become confused by the extra ultraviolet light, so make sure that you brush away any snow from around the hive and erect a shade over the entrance.

- Brush away any snow from the entrance and from around the front of the hive
- Check hives regularly for storm and wind damage
- Make sure that the mouse guard is still in place
- Check that overhanging branches have not been damaged by storms and that they cannot drop on to the hive
- If you have a WBC-type hive look under the roof to make sure there is nothing hibernating there
- Look out for signs of flight on warm days, and observe any flying bees for vitality

Checklist

- Clean your equipment
- Build new frames and hives
- Read up on beekeeping
- Watch out for signs of attack by mammals – mice, badgers or people

Late winter

In late winter the queen will be beginning to lay again to produce the house bees that will take advantage of the first pollen flows of spring. This can a difficult time for your bees, but you must resist the temptation to open the hive. If you are really worried about starvation, get some help from an experienced beekeeper.

This is usually a quiet time of year, so take the opportunity to repair any spare hives, bring your records up to date and prepare frames with foundation.

- Check your hives for signs of storm damage
- Look out for signs of activity in the hive as winter-flowering bulbs come into bloom
- Make sure that you provide food for the hive
- Make sure that your bees have access to unfrozen water in a sunny spot

Right: *The beehive in winter is still: you would hardly know there were hundreds of bees alive inside the box.*

Recipes

If you are one of the many people who enjoy honey on toast for breakfast but then put away the jar when you are cooking, it's time to think again. Honey has been used to sweeten dishes from the times of the ancient Egyptians, and if you have your own supply you can use it in numerous dishes, ranging from simple breakfast cereals to sticky cakes and delicious ice cream.

Orange Flower and Honey Baklava

Prep time 40 mins, plus cooling
Cook time about 1 hour
Makes about 20 pieces

250 g (8 oz) blanched almonds
150 g (5 oz) blanched hazelnuts
75 g (3 oz) caster sugar
150 g (5 oz) unsalted butter, plus extra for greasing
50 ml (2 fl oz) extra virgin olive oil
22 sheets, about 300 g (10 oz), filo pastry (thawed if frozen)

SYRUP
300 g (10 oz) caster sugar
250 ml (8 fl oz) water
50 ml (2 fl oz) extra virgin olive oil
50 ml (2 fl oz) orange flower water
finely grated rind of 1 lemon
3 tablespoons clear honey
1 cinnamon stick

1 Make the syrup. Combine all the ingredients in a small saucepan and heat gently, stirring occasionally, until the sugar has dissolved. Increase the heat slightly and leave to bubble gently, without stirring, for about 20 minutes until it forms a light, sticky syrup. Remove the pan from the heat and allow the syrup to cool in the pan. Cover the pan and chill in the refrigerator, without straining.
2 Meanwhile, put the almonds, hazelnuts and sugar in a food processor or blender and process until the nuts are chopped but not ground.
3 Melt the butter with the olive oil in a heavy-based saucepan over a low heat and brush a sheet of filo pastry with the mixture, keeping the remaining pastry covered with a damp tea towel. Butter a 20 x 30 x 5 cm (8 x 12 x 2½ inch) tin and line it with the pastry, trimming it to fit the tin but leaving a little extra to allow for shrinkage during cooking. Repeat the process with 4 more sheets of pastry, brushing them with the butter and oil mixture as you layer them.
4 Scatter one-third of the nuts over the pastry and cover them with 5 more sheets of pastry, brushing each with the butter and oil mixture as you work. Add half the remaining nuts and cover them with 5 more sheets of pastry, the remaining nuts and then the remaining 7 sheets of pastry. Brush the top liberally with the remaining butter and oil mixture. Use a sharp knife to cut through the top few layers of pastry in a crisscross pattern to make about 20 diamond shapes.
5 Bake in a preheated oven, 190°C (375°F), Gas Mark 5, for about 40 minutes until golden. Remove the cinnamon and lemon rind from the syrup, and as soon as you take the baklava from the oven pour the syrup evenly over it. Leave to cool, then cut the baklava into the scored diamonds.

Honeyed Cereal

Prep time 10 mins
Cook time 20 mins
Serves 4

4 tablespoons sunflower or safflower oil
250 g (8 oz) clear honey
250 g (8 oz) millet, rye or barley flakes
250 g (8 oz) rolled oats
50 g (2 oz) sesame seeds
50 g (2 oz) dried peaches, banana slices, pears or figs, chopped
125 g (4 oz) sultanas or seedless raisins
25 g (1 oz) coconut shavings
50 g (2 oz) pumpkin seeds
milk, to serve

1 Heat the oil in a small roasting tin, then stir in the honey, flakes, oats and sesame seeds. Cook in a preheated oven, 180°C (350°F), Gas Mark 4, for 20 minutes, stirring occasionally so the mixture browns evenly.
2 Remove the tin from the oven and leave to cool. Mix in the dried fruit, sultanas or raisins, coconut shavings and pumpkin seeds. Store in an airtight container until required, then serve with milk.

Honey Cinnamon Biscuits

Prep time 15 mins, plus chilling
Cook time 12–15 mins
Makes 20 biscuits

125 g (4 oz) plain flour
75g (3 oz) unsalted butter, diced, plus extra for greasing
¼ teaspoon ground cinnamon
3 tablespoons set honey

ICING
250 g (8 oz) icing sugar
1 tablespoon clear honey
lemon juice
pared rind of 1 lemon (optional)

1 Sift the flour into a bowl and rub in the butter. Add the cinnamon and mix in the honey to make a soft dough. Shape the dough into a roll about 20 cm (8 inches) long and wrap it in clingfilm. Chill until firm.
2 Lightly grease 2 baking sheets. Cut the dough into 20 slices and place them slightly apart on the baking sheets. Bake in a preheated oven, 190°C (375°F), Gas Mark 5, for 12–15 minutes. Leave on the baking sheets to cool slightly, then transfer to a wire rack to allow the biscuits to cool completely.
3 Make the icing. Sift the icing sugar into a bowl and gradually beat in the honey and enough lemon juice to make a thick glacé icing. Spread a little over each biscuit and leave to set. Decorate the biscuits with fine strips of boiled lemon rind, if liked.

Carrot, Honey and Sultana Squares

Prep time 10 mins, plus decorating
Cook time 20–25 mins
Makes 15 cakes

150 ml (¼ pint) sunflower oil, plus extra for greasing
3 eggs
125 g (4 oz) set or clear honey
50 g (2 oz) light muscovado sugar
200 g (7 oz) wholemeal self-raising flour
2 teaspoons baking powder
3 carrots, about 200 g (7 oz) in total, peeled and grated
100 g (3½ oz) sultanas

TO DECORATE
100 g (3½ oz) unsalted butter, at room temperature
finely grated rind and juice of ½ orange
200 g (7 oz) icing sugar, sifted
large and small candy-coated chocolate sweets

1 In a large bowl mix together the oil, eggs, honey and sugar. Add the flour and baking powder and mix well, then stir in the grated carrots and the sultanas.
2 Lightly grease and line a rectangular baking tin. Pour the cake mixture into the tin and smooth flat. Bake in a preheated oven, 180°C (350°F), Gas Mark 4, for 20–25 minutes until it is well risen and golden brown and the top springs back when lightly pressed. Leave the cake to cool in the tin for 10 minutes, then turn out on to a wire rack. Remove the lining paper.
3 Make the icing. Mix together the butter and orange rind in a medium-sized bowl. Gradually mix in the icing sugar and enough of the orange juice to make a soft, spreadable icing. Spread on the cake and cut into 15 squares. Decorate each square with the sweets.

Really Fruity Flapjacks

Prep time 15 mins
Cook time about 20 mins
Makes 15–20 flapjacks

100 g (3½ oz) unsalted butter
100 g (3½ oz) light muscovado sugar
5 tablespoons clear honey
375 g (12 oz) porridge oats
75 g (3 oz) ready-to-eat dried prunes, chopped
75 g (3 oz) ready-to-eat dried apricots, chopped
75 g (3 oz) raisins or sultanas
2 eggs, lightly beaten

1 Put the butter, sugar and honey in a small, heavy-based saucepan and heat gently, stirring. Remove from the heat and mix in the oats, prunes, apricots and raisins or sultanas until evenly mixed. Beat in the eggs.
2 Lightly grease a shallow 28 x 23 cm (11 x 9 inch) baking tin. Turn the mixture into the tin and level the surface. Bake in a preheated oven, 180°C (350°F), Gas Mark 4, for 20 minutes or until turning pale golden.
3 Leave in the tin until almost cold, then cut into fingers and transfer to a wire rack until they are completely cool. The flapjacks can be stored in an airtight container in a cool place for up to 5 days.

Pear, Cardamom and Sultana Cake

Prep time 20 mins
Cook time 1¼–1½ hours
Serves 12

125 g (4 oz) unsalted butter, softened
125 g (4 oz) soft light brown sugar
2 eggs, lightly beaten
250 g (8 oz) self-raising flour
1 teaspoon ground cardamom
4 tablespoons milk
500 g (1 lb) pears, peeled, cored and thinly sliced
125 g (4 oz) sultanas
1 tablespoon clear honey

1 In a large bowl mix together the butter and sugar until they are pale and light. Beat in the eggs a little at a time. Sift together the flour and ground cardamom and fold them into the creamed mixture together with the milk.
2 Reserve about one-third of the pear slices and roughly chop the rest. Fold the chopped pears into the creamed mixture with the sultanas.
3 Lightly oil and base-line a 1 kg (2 lb) loaf tin and spoon the mixture into the tin. Smooth the surface, making a small dip in the centre. Arrange the reserved pear slices down the centre of the cake, pressing them in gently. Bake in a preheated oven, 160°C (325°F), Gas Mark 3, for 1¼–1½ hours or until a skewer inserted into the centre comes out clean.
4 Remove the cake from the oven and drizzle over the honey. Leave to cool in the tin for 20 minutes and then transfer to a wire rack until it is completely cool.

Lavender Honey Ice Cream

Prep time 20 mins, plus chilling and freezing
Cook time 15 mins
Serves 4

6 tablespoons lavender honey
4 egg yolks
1 teaspoon cornflour
1 tablespoon caster sugar
300 ml (½ pint) milk
300 ml (½ pint) double or whipping cream
lavender sprigs, to decorate (optional)

1 Put the honey, egg yolks, cornflour and sugar in a bowl and whisk lightly to combine.
2 Put the milk in a heavy-based saucepan and bring it to the boil. Pour the milk over the egg yolk mixture, whisking well until it is combined. Return the mixture to the saucepan and cook gently, stirring, until the custard has thickened and coats the back of the spoon thinly.
3 Transfer the mixture to a bowl and cover with a round of greaseproof paper to prevent a skin from forming. Leave to cool, then transfer to the refrigerator to chill.
4 Transfer the custard to an ice cream maker and add the cream. Churn until frozen. Alternatively, beat the custard and cream together and put in the freezer, beating the ice cream after an hour to break down any ice crystals.
5 Serve the ice cream in glasses decorated with lavender sprigs, if liked.

Figs with Yogurt and Honey

Prep time 5 mins
Cook time 10 mins
Serves 4

8 ripe figs
4 tablespoons plain yogurt
2 tablespoons honey

1 Place the figs on a foil-lined grill pan and cook them under a preheated medium grill for 8 minutes, turning occasionally, until they are charred on the outside. Remove and cut them in half.
2 Arrange the halved figs on 4 plates and serve with a spoonful of plain yogurt and some honey spooned over the top.

Walnut and Honey Yogurt

Prep time 2 mins, plus chilling
Serves 1

1 dessertspoon honeycomb
100–200 g (3½–7 oz) low-fat, thick natural yogurt
6–7 walnut halves

1 Cut the honeycomb into pieces to release the liquid honey from the cells.
2 Stir the honey into the yogurt with the walnut halves and chill until ready to serve.

Hot Honey and Lemon Drink

Prep time 2 mins
Serves 1

2 tablespoons lemon juice
2 tablespoons set honey
boiling water

1 Mix together the lemon juice and honey in a mug.
2 Gradually pour in the boiling water, stirring to dissolve the honey, until the mug is almost full. Drink as hot as you can, but remember to allow it to cool for children.

Banana and Honey Shake

Prep time 2–3 mins
Serves 2

2 bananas
2 tablespoons clear honey
300 ml (½ pint) milk
2 ice cubes

1 Peel and slice the bananas and put them into a liquidizer or blender. Add the honey and milk and process until smooth.
2 Pour the mixture into individual glasses and add an ice cube in each. Serve with drinking straws.

Mead

Prep time 2 hours plus 1 year to mature
Makes approximately 5 litre bottle

5 litres (1.1 gallons) water
1.2 kg (2½ lb) honey
juice of 1 lemon
1 vitamin C tablet
1 teaspoon wine yeast

1 Put the water, honey, lemon juice and vitamin C tablet in a large, heavy-based saucepan and bring to the boil to kill the natural yeasts. (You can sterilize the mixture with the appropriate number of proprietary sterilizing tablets if you prefer.)
2 Leave the liquid to cool, then transfer it to a sterilized demijohn. Add the wine yeast and close with a sterilized airlock. The fermentation will take place for around 2 weeks and then the lees will start to settle.
3 Rack (siphon) off the liquid into another sterilized demijohn and store in a cool, dark place. (If you can manage to store it on a heavy stone floor the sediment will fall more easily.) Rack off the mead again.
4 When the liquid is clear transfer it to bottles and store for at least a year – if you can manage to resist it!

Acaricide A preparation used to destroy mites.

Acarine A disease caused by mites (*Acarapis woodi*) that affects a bee's breathing tubes. It is sometimes known as Isle of Wight disease because it was first seen there in 1906.

Africanized bees Also, colloquially (if misleadingly), known as killer bees. A hybrid between the African honeybee (*Apis mellifera scutellata*) and several European honeybees. These bees, which have a reputation for being more aggressive in defence of their hives than European honeybees, have spread both north and south from Brazil, where the hybrids first occurred, and it is not known, given climate change, how much further they will spread.

American foul brood A notifiable disease, which may occur anywhere in the world, AFB is caused by *Paenibacillus larvae*, a spore-producing bacterium. The spores develop in the gut of larvae, which die in their cells, the cell caps appearing darker and sunken and often perforated. There is no known treatment, and infected hives, both stock and frames, must be destroyed. See also European foul brood.

Anther The part of a flower that releases pollen.

Bee brush A very soft brush or a large feather used to remove bees from the frame or to coax them into a confined space.

Bee cage A device for safely introducing a new queen into a hive. It is a mesh cage, which enables the other bees to lick the queen and pass her pheromones around the hive without harming her. The cage can be positioned between the frames of the brood chamber. The queen is kept inside the cage by a plug of newspaper or sugar candy, which the beekeeper can remove after a few days or allow the bees themselves to chew away.

Bee space The space of 7–8 mm (about ¼ inch) between the frames and walls of a hive that will not be filled with propolis (if smaller) or honeycomb (if larger), enabling the beekeeper easily to remove the frames. The space was first identified by the Rev. Lorenzo Lorraine Langstroth, a beekeeper in Philadelphia, in the early 1850s.

Beeswax A substance produced by eight glands on the underside of the abdomen of worker bees and used by bees to cap cells and build comb.

Bottom bee space hive A hive in which the frames hang in the boxes with a space between the bottom of the frames and the box. This style is most often seen in National-type hives. See also top bee space hive.

Brace comb A bridge of wax built between surfaces within the hive.

Brood The immature stage of the bee (eggs, larvae and pupae) in cells that may be uncapped or unsealed (eggs and larvae) or capped or sealed (larvae that will pupate into adult bees).

Brood box The part of the hive in which the queen is confined (by

a queen excluder) and the brood is reared. A hive may contain more than one brood box.

Candy A solid food made from sugar, more frequently used to separate queens in a new hive.

Chalk brood A fungal infection, caused by *Ascosphaera apis*, which 'mummifies' larvae in the brood frame. Although it is occasionally confused with American foul brood, it is not as serious and may often be overcome by re-queening.

Clearer board A board used to remove bees from supers before the honey is harvested. The board will have one or more bee escapes, which allow bees to pass through but prevent them from returning.

Crown board Also known as the inner cover. The board that is placed on the top super and below the roof of the hive. The board has a hole in it for ventilation.

Drone A male bee. Unlike queen and worker bees, a drone has no sting.

European foul brood A notifiable disease, EFB is caused by the bacterium *Melissococcus pluton*, which infects the guts of developing larvae and competes with them for food. Not all infected larvae will die, and bees often eject the infected larvae themselves. However, if infected larvae survive to the pre-pupal stage, spores will be voided into the cells, infecting other larvae. A heavily infected hive should be destroyed, but in the early stages of infection shaking the swarm into a new hive is likely to be effective. See also American foul brood.

Exoskeleton The hard outside covering of an insect's body that protects and supports the insect.

Feeder One of two types are usually used, a large rectangular or smaller round version. They are filled with sugar syrup to feed the bees.

Flight board The wooden strip in front of the hive on which bees land.

Foundation A wax sheet embossed with a hexagonal pattern used as the basis for bees to build comb.

Frame A wooden or plastic structure that holds the wax comb and allows the beekeeper to remove the comb from the hive to inspect it. The beekeeper usually makes their own frames.

Guard bees Bees that wait at the entrance to the hive to protect it from foreign bees, wasps and animals. These bees release pheromones to alert the other bees in the hive if the colony is threatened.

Hefting The practice of lifting your hive with the roof on but with no supers in it as a way of establishing its weight. With practice, this enables the beekeeper to determine the weight of the colony and its food supplies.

Hive tool A metal tool used by beekeepers for levering and separating frames.

Hoffman frame A type of self-spacing frame.

Honey flow The period during which the supply of nectar from flowers is at its peak.

Landing board Also known as alighting board. The strip of wood that is attached to the bottom of the hive on which bees land before they enter the hive. It enables the beekeeper to see what bees are removing from the hive.

Langstroth hive The most commonly used type of hive in North America.

Mouse guard A grid allowing bees in and out of the hive while excluding mice.

Nasonov gland A gland on the abdomen of a worker bee that secretes a substance used to attract bees back to their hive.

National hive A square, single-walled hive; it is the most widely used hive in Britain.

Nectar The sugary substance that is produced by plants in order to attract pollinating insects and that is made into honey by bees.

Nosema A disease caused by a protozoan (*Nosema apis*), which affects the gut of adult bees.

Nurse bee The name given to a worker bee that helps to rear brood in the hive.

Oilseed rape The yellow flowers of this important agricultural crop, *Brassica napus*, are a good source of pollen, but the honey produced crystallizes quickly and sets so hard that bees cannot get it out of the combs. If your bees are near crops of OSR you must be ready to take the honey from the hive early in the season. Also bear in mind that farmers are likely to apply pesticides to their OSR crops, which will not only kill wild bees but could well destroy your own colony.

Open mesh floor A fine mesh floor that is used to both improve ventilation in the hive and help control varroa mites, which fall through the mesh but are unable to return to the hive.

Pistil The female reproductive organ of a flower.

Pollen The dust-like grains that are produced by a flower's anthers (the male part of a flower) and that are used to fertilize the female ovule.

Pollen basket Also known as pollen sac. The area on the hind leg of a bee in which pollen is transported to the hive. The basket, actually a hollow in the tibia, is surrounded by brush-like hairs, which enable the bee to scrape the pollen caught on its body hairs into the basket.

Porter bee escape A one-way bee escape, often used on clearer boards, that allow bees to exit but not return.

Propolis Also known as bee gum or bee glue. The reddish or black-brown resinous substance that is collected by bees from plants, such as from the buds of *Aesculus hippocastanum* (horse chestnut), and used in the construction of the hive.

Queen The sexually developed female bee that lays eggs.

Queen cell A large cell on the face or bottom of the frame that houses a grub destined to become a queen.

Queen excluder A screen with slots or a mesh that allows worker bees to pass through it but can be positioned to exclude the queen and drones from parts of the hive.

Queen marking grid A device for holding a queen on the frame surface allowing you to mark her. Marking sets the queen's age and makes her more visible.

Robbing The taking of honey from a hive by wasps or bees from another colony.

Royal jelly Also known as bee milk. The substance secreted by the worker bees and fed to future queens.

Sac brood A viral disease that causes larvae to die before their final moult. Re-queening is usually effective.

Skep An old-fashioned type of hive, made of wicker or straw

and without movable frames, which the beekeeper can use to take swarms.

Smoker The device used by beekeepers to introduce cool smoke into a hive to calm bees before the hive is opened. Suitable materials to burn include wood shavings, newspaper, egg boxes, old hessian sacking, dried conifer clippings and dried grass cuttings.

Stigma The part of a flower's pistil that receives the pollen during pollination.

Sting Queen and worker bees, but not the drones, have a barbed sting. When the sting is used, it is left in the wound together with parts of the bee's viscera. This means that after the bee has stung it will die.

Sugar syrup A solution of 50:50 sugar : water, used to feed bees in times when no nectar is flowing or honey supplies are low.

Super The chamber or chambers above the brood box in which honey is kept.

Supersedure The process of removing a queen and replacing her with a new one without the colony swarming.

Sulphur candle A device for killing off a whole colony if some disease problem makes it necessary.

Swarm A mass of bees that is not in a hive. The bees could be attempting to establish a new colony or escaping from an unsatisfactory hive. Ideally, a swarm includes a mated queen.

Top bee space hive A hive in which the frames are suspended so that there is a space between the top of the frames and the top of the box. This arrangement is most often seen in Langstroth-type hives. See also bottom bee space hive.

Varroa destructor The mite that breeds in sealed brood cells.

Varroa strips A plastic strip impregnated with insecticide that will selectively kill varroa mites in the hive.

Varroosis The disease of bees caused by the parasitic mite *Varroa destructor*.

Waggle dance A circular or figure-of-eight dance performed by the bees. They use this movement to communicate with other bees the distance and direction of a food source from the hive.

Wax moths Both the lesser (*Achroia grisella*) and greater (*Galleria mellonella*) wax moth are serious pests in the hive, where they damage stored comb. The larvae manage to scoop out indentations in the wooden sides of frames and hives (including those that are in storage) where they pupate.

WBC hive A double-walled hive, designed by William Broughton Carr in 1890, which is often included in gardens because of its attractive, pagoda-like appearance.

Worker An immature female bee. Worker bees are the most numerous residents of a hive.

Keeping bees is a wonderfully relaxing and rewarding pursuit. Whether you have a large garden, small backyard or roof terrace there is enough room for a hive or two – and that is all you need to produce delicious honey.

Suitable for both the beginner and the experienced beekeeper, this practical guide covers everything from setting up and locating a hive to harvesting honey and wax.

- Step-by-step photographs on how to handle and check your bees
- Seasonal tasks and checklists tell you what you need to do and when
- Delicious recipes using your homemade honey

INTRODUCTION

How to Use This Manual

This manual contains the information needed to become a certified commercial applicator in Category 1A, Field Crops. This manual is intended for use in combination with the *Pesticide Applicator Core Training Manual* (Extension bulletin E-2195), available through the Michigan State University Bulletin Office. However, this manual would also be useful to anyone interested in learning more about field crop pest management.

Category 1A, Field Crops, covers the management and control of common pests in alfalfa, corn, dry beans, soybeans, small grains, and sugarbeets. The manual presents basic scientific information on pest life cycles and emphasizes protecting non-target organisms and preventing the development of resistance in pests.

The Category 1A certification exam is based on information found in this booklet. Each chapter begins with a set of learning objectives that help you focus on what you should understand from each chapter. The table of contents helps you identify important topics and understand how they relate to one another through the organization of headings and subheadings. As you prepare for the exam, read each chapter and answer the review questions. These questions are not on the certification exam. They are provided to help you prepare for the exam. Questions on the exam will pertain directly to the learning objectives.

The appendices and glossary, including an answer key (Appendix A), at the end of this manual provide supplemental information that will help you understand the topics covered in the chapters. Terms throughout the manual text that are bold and italicized can also be found in the glossary.

This certification manual benefits the applicator and the general public. By learning how to handle pesticides correctly, applicators can protect themselves, others, and the environment from pesticide misuse. For more specific information on how to become a certified applicator in Michigan, refer to the beginning of the core manual (E-2195) or the Michigan Department of Agriculture's Web site, <http://www.mda.state.mi.us>, or call the MDA at 1-800-292-3939.

CHAPTER 1

INTEGRATED PEST MANAGEMENT

LEARNING OBJECTIVES

After completely studying this chapter, you should:

- Be able to define integrated pest management.
- Understand the importance of an economic threshold.
- Know the basic principles of field scouting.
- Know the three ways that cultural control methods work.
- Be able to define and give examples of a natural enemy.
- Understand the various types of pesticides.
- Understand the importance of preharvest interval, residues, reentry interval, phytotoxicity, and pesticide resistance.

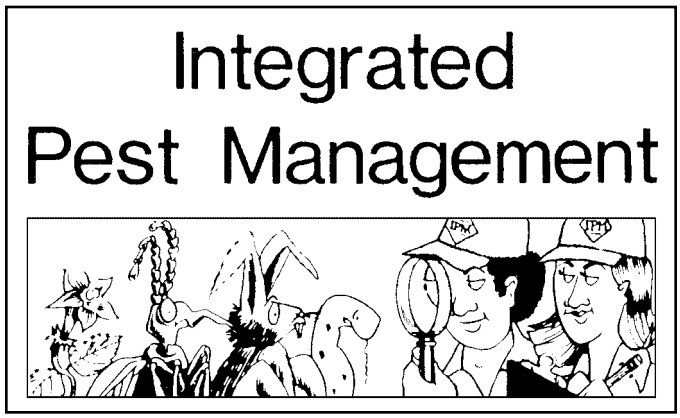
Field crops are vulnerable to attack by pests. Pest damage can range from slight damage that has no effect on the value of the harvested product to severe damage that kills plants, significantly reduces yield of the crop, or reduces its market value. Field crop pests include insects and mites, weeds, diseases, and nematodes.

Effective management of pests is based on thorough consideration of ecological and economic factors. The pest, its biology, and the type of damage are some of the factors that determine which control strategies and methods, if any, should be used. Pest management decisions largely determine the kind and amount of pesticides used.

Pest management decisions represent a compromise between the value of the product, the extent of the pest damage, the relative effectiveness and cost of the control measures, and the impact on the environment.

INTEGRATED PEST MANAGEMENT (IPM)

The goal of IPM is to use all appropriate tools and tactics to keep pest populations below economically damaging levels and to avoid adverse effects to humans, wildlife, and the environment. These tools include cultural, biological, and chemical control methods. Management decisions are based on information gathered about the pest problem and crop. Then you use a combination of control measures that best suits the problem.

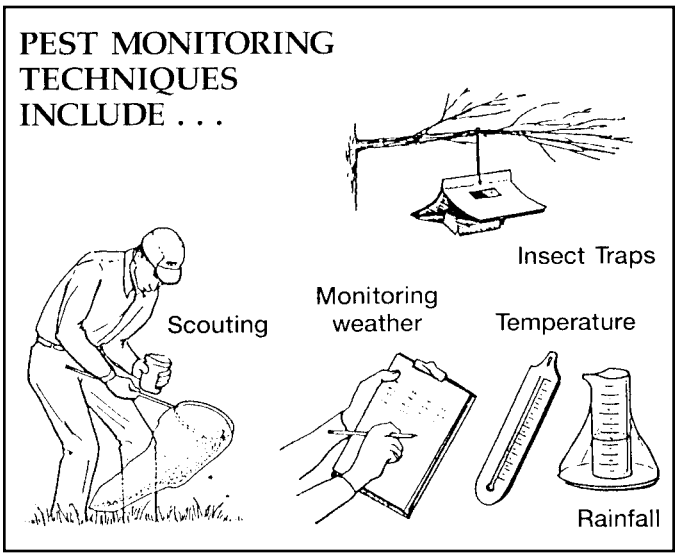


What are these IPM tools and how are they used?

FIELD SCOUTING, MONITORING

Field scouting is an important part of any IPM program because it helps define the pest problems. Correct identification and location of each pest in a crop are necessary for a successful pest management program. These can be accomplished by regularly scouting fields. A scouting trip through a field reveals what pests are present, the growth stage of the pests and the crop, the location of the pest in the crop, whether the pests are parasitized or diseased, the pest population, if the population is increasing or decreasing, and crop condition. A scouting program should include accurately written records of

field locations, field conditions, previous pest infestations, and control measures. Using this information, you can decide what control measures are needed and will be the most effective.



Remember the following basic principles when scouting:

- Take samples from several areas of the field.
- Select sample sites at random unless field conditions suggest uneven pest distribution.
- DO NOT sample in border rows or field edges unless indicated to do so for a particular pest.

Insect pests can be monitored in several ways. The most common methods are directly counting the number of insects present and / or estimating the amount of insect damage. Insect counts are usually expressed as the number of insects per plant or plant part (e.g., number of insects per leaf); insect crop damage is often expressed as percentage of the plant damaged (for example, percent leaf defoliation). Other scouting methods include collecting insects with a sweep net, shaking crop foliage and counting dislodged insects, and trapping insects.

ECONOMIC THRESHOLDS

An **economic threshold** is defined as the pest density at which action must be taken to prevent the pest population from increasing and causing economic damage. Economic thresholds are constantly changing. They vary between fields, varieties, and crop growth stages. Economic thresholds are a function of crop value and cost of control. In general, a high-value crop will have a lower economic threshold; less pest damage will be accepted and control measures must be taken sooner. If the control measures are expensive, the economic threshold is usually high. High control costs mean it takes more crop loss to justify the control action.

Economic thresholds are often referred to as **action thresholds**. When the pest population reaches the threshold, action is taken to reduce the population. For insects, an economic or action threshold is typically expressed as the number of insects per plant or the amount of crop damage.

CONTROL STRATEGIES

CULTURAL CONTROL

Cultural control uses farming practices to reduce pest populations. Implementing a practice such as tillage or crop rotation at the correct time can kill or reduce pest numbers or slow pest development. Like all other control strategies, cultural control requires an understanding of the pest and the crop. Cultural control measures are usually applied at the weakest stage of the pest's life cycle. Generally, cultural control methods are preventive actions rather than curative actions.

Cultural control methods work in three ways:

1. Prevent the pest from colonizing the crop or commodity.
2. Create adverse conditions that reduce survival of the pest.
3. Reduce the impact of pest injury.

PREVENTING COLONIZATION

Control measures that prevent colonization physically exclude the pest, reduce pest populations, prevent the pest from finding the crop, or disrupt the timing between the pest and the crop.

A. Trap crop—planting a small area with a preferred host to attract the pest away from the crop. Once in the trap crop, the pest can be destroyed or controlled.

Alfalfa and wheat strips border a sugar beet field.

B. Physical barriers—separating a pest and host with an object such as a wall to stop the pest from infesting. Example: in grain bins, it is extremely important to fill in all cracks and crevices with approved caulking material to prevent colonization by pests such as insects and rodents.

C. Crop rotation—a cycle in which different crops are planted in a field every year; the longer the rotation, the

better the pest control. A crop rotation system helps control host-specific pests. A classic example of crop rotations is a corn-soybean rotation to control corn rootworms.

D. Delayed planting (timing)—changing the planting date so that the host is not available when the pest is present. Example: changing the planting date of winter wheat can control the Hessian fly. The adult fly is short-lived and requires wheat at a specific vegetative state for egg laying. Delaying the fall planting of winter wheat until after the Hessian fly adults have died offers year-round control of this pest. Another example is planting oats before May 15 to reduce the crop's exposure to aphids carrying barley yellow dwarf virus when the plants are young and more susceptible.

Red clover cover crop growing in spelt stubble.

E. Cover crops—utilizing plant competition by planting a secondary crop to prevent weeds from becoming established. Example: cereal grain cover crops provide a suitable environment for soybean seedling establishment while suppressing weeds.

CREATING ADVERSE PEST CONDITIONS IN THE CROP

Pests require specific living conditions. Cultural control methods can disrupt ideal pest conditions and so decrease pest pressure. Adverse pest conditions can be created by destroying the host plant, physically moving the soil, changing water management practices and spatial arrangement, and the plant's natural defense mechanisms.

A. Destroy crop residue, alternate hosts, and volunteer crops—eliminating the pest or pest habitat found in crop residue, or destroying alternate hosts of the pest found near or in the crop. Example: planting wheat into corn residue increases the risk of wheat scab because the pathogen infects both hosts.

Pests, particularly plant pathogens, can survive in a field on volunteer crops and alternate hosts. The survival of these pathogens provides a source of inoculum for the field. For example, wheat streak mosaic virus and its mite vector survive on volunteer wheat. Many fungi and bacteria build up on volunteer crops early in the season and surround and infect the crop later in the season.

B. Tillage—physically moving the soil around the crop. Tillage can destroy an insect, create physical and chemical changes in the soil that reduce pathogens, and destroy a weed's roots and disrupt nutrient uptake. All of these factors can reduce pest populations.

C. Water management—manipulating water to control a pest. For example, fungal pathogens that infect pests such as the velvetbean caterpillar in soybeans are easily spread by overhead sprinkler irrigation. Water management can also be used to promote healthy crops, which are better able to compete with weeds. Overwatering can increase the potential for plant diseases.

D. Spatial arrangement (seeding rate and row spacing)—changing the spatial arrangement of the crop to reduce pest populations. Example: when plant spacing and row width are reduced, soybeans outcompete weeds. On the other hand, close spacing may provide a favorable environment for disease to develop—for example, white mold in soybeans and dry beans.

E. Allelopathy—one plant species eliminates a competing plant species through the release of toxic chemical agents. Allelopathy has great potential in weed management. For example, in a conservation tillage system, leaving rye residues can reduce the number of weeds.

REDUCE PEST INJURY TO CROP

Cultural controls also utilize a plant's defense mechanisms to minimize pest damage. Planting pest-resistant crops, maintaining a healthy crop, timing harvest to reduce pest damage, and practicing pest-reducing storage techniques can reduce pest injury.

A. Host-plant resistance—the host plant's ability to tolerate pest pressure. Plants have defense mechanisms that allow them either to affect the pest or withstand the pest's damage.

B. Plant health—maintaining strong, healthy plants that are better equipped to out-compete weeds, fight disease, and withstand insect damage.

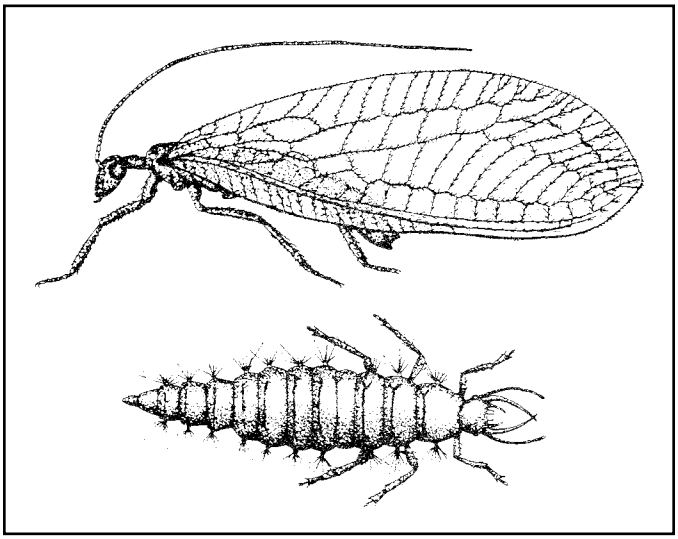
C. Harvest timing—changing the time when a crop is harvested to reduce pest impact on yield. For example, cutting alfalfa early can reduce the effects of alfalfa weevil or leafhopper damage. Cutting too early, however, weakens the roots and can make the plant more susceptible to root diseases.

D. Storage practices—handling, curing, and storage practices to prevent the spread of disease during storage. For example, low temperature and good ventilation are essential to minimize losses in potatoes.

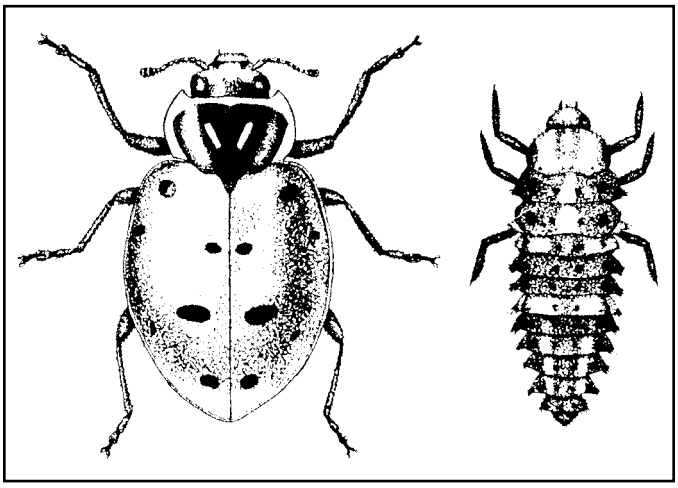
BIOLOGICAL CONTROL

Biological control is the use of living **organisms** to reduce a pest population. These beneficial (good) organisms are referred to as natural enemies. Predators, parasitoids, and pathogens are the most common natural enemies.

- **Predator**s—other organisms that eat the pest. Predators are usually not specific about what they eat—they will eat a variety of pests.

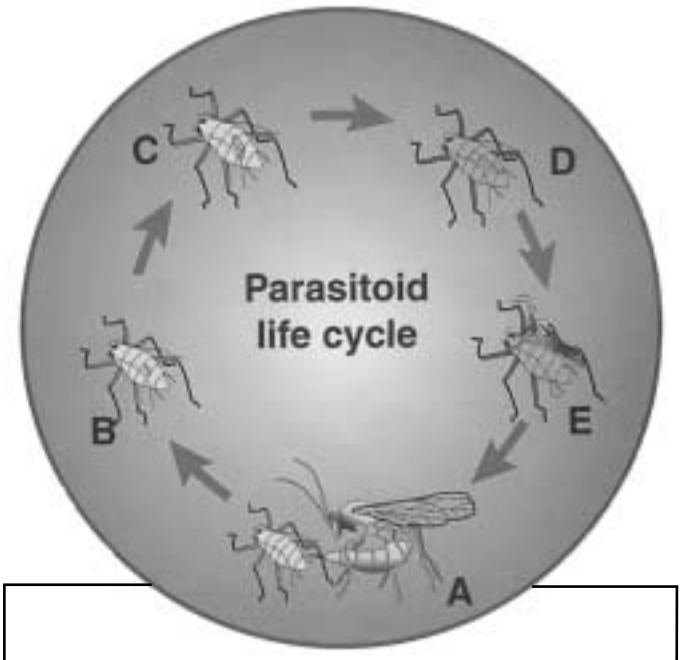


Green lacewing adults and larvae eat a variety of insects.



Ladybird beetle adults and larvae consume large numbers of aphids and mites.

- **Parasitoids**—organisms that must live in or on another organism to develop. A parasitoid is usually an insect that develops and feeds inside another insect. An adult parasitoid lays an egg in or on a host insect. When the parasitoid egg hatches, the larva feeds on the host insect. Eventually, the developing parasitoid kills the host insect by eating it from the inside out. Common parasitoids include tiny wasps and flies. They are usually host specific.



A. Wasp lays egg in host (for example, an aphid).
B., C. As the host feeds and grows, so does the wasp larva.
D. Parasitoid kills then pupates within dead host.
E. An adult parasitoid emerges from the dead host.

- **Pathogens**—disease-causing organisms such as bacteria, viruses, and fungi that infect and kill the pest. Environmental conditions such as high humidity or high pest abundance allow naturally occurring pathogens to multiply and cause disease outbreaks (**epizootic**) that reduce a pest population. Some insect pathogens are manipulated to control specific pests. For example, the soil bacterium *Bacillus thuringiensis* (commonly known as Bt) can kill a variety of insects, including many caterpillars and mosquito and beetle larvae.

Examples of insect biological control agents (natural enemies).

Natural Enemy	Pests Controlled
PREDATORS	
lady beetles	aphids, scale insects
green lacewings	aphids, mites, others
spined soldier bug	Colorado potato beetle, Mexican bean beetle
minute pirate bug	corn earworm eggs, mites
PARASITOIDS	
tachinid flies	beetles, caterpillars
ichneumonid wasps	caterpillars, leafrollers, weevils, others
braconid wasps	caterpillars, beetles, aphids
Trichogramma wasps	eggs of moths, such as European corn borer
PATHOGENS	
Bacillus thuringiensis	caterpillars, some beetle larvae
nuclear polyhedrosis viruses (NPV)	caterpillars
Beauveria bassiana (fungus)	caterpillars, grasshoppers, aphids
Nosema (protozoan)	caterpillars, beetles, grasshoppers

CHEMICAL CONTROL

Chemical control reduces a pest population through the application of pesticides. The decision to use a pesticide as part of an IPM program should be based on a scouting program, pest identification, economic thresholds, and the crop/pest life stage. When used properly, pesticides provide effective and reliable control of most pest species.

TYPES OF PESTICIDES

Pesticides used to control field crop pests are applied either to the soil or to the plant foliage.

■ **Soil-applied pesticides**

Chemigation—applying a pesticide or fertilizer to the soil by injecting it into the irrigation system.

Insecticides—applied to prevent insect damage to the roots of corn and other crops. Insecticides can be applied by broadcast soil applications and soil incorporation before planting, applied in the seed furrow at planting, or broadcast before or after crop emergence.

Herbicides—applied to the soil surface and mixed into the soil before planting (**preplant incorporated**) or applied after planting but before crop emergence and not incorporated (**preemergence**).

Soil fumigants or nematicides—applied to the soil to control nematodes.

■ **Foliar-applied pesticides**

Most foliar applications are broadcast liquid pesticides applied directly to the crop or pest. They can be applied before damage occurs (**preventive**) or in response to damage (**curative**).

Insecticides—generally applied to control insects feeding aboveground on the crop.

Herbicides—applied to the weed foliage after the crop and weeds have emerged (**postemergence**).

Fungicides—can be applied to the crop before the disease appears (**protectant**) or to remove the disease after it appears (**eradicant**).

The following are special considerations to remember when using a pesticide to control your pest problem:

Preharvest interval—the minimum number of days needed between the last pesticide application and harvest. The Environmental Protection Agency (EPA) requires that all pesticide labels state the preharvest intervals for each crop. The preharvest interval is based partly on how long it takes the pesticide to break down. Observing the preharvest interval reduces pesticide residue on the commodity.

Residues—the pesticide that remains on the crop after an application. Ideally, a pesticide is present only long enough to kill the pest and then breaks down. Unfortunately, many pesticides do not break down completely before harvest. Therefore, for each pesticide registered for use on a food or feed crop, the EPA sets the amount of acceptable residue (tolerance) permitted on the harvested crop. The amount of residue relates to the preharvest interval and the pesticide application rate. Harvesting a crop during the preharvest interval or applying more pesticide than the label stipulates increases the potential for residues to exceed legal tolerance levels.

Reentry interval (REI)—the amount of time required after a pesticide application before a person can reenter a field without personal protective equipment (PPE). The reentry interval prevents unnecessary pesticide exposure. Only workers trained for early entry under the Worker Protection Standards (WPS) and wearing proper PPE may enter a treated area during the reentry interval. Refer to the Worker Protection Standards (WPS) for the regulations on informing workers about pesticide applications.

Phytotoxicity—when a pesticide damages the crop to which it is applied. Pesticide drift, excessive rates, mixing incompatible pesticides, and improper calibration can all cause phytotoxicity. Weather conditions can increase the degree of damage caused by phytotoxicity. For example, cooler weather followed by a period of bright, hot, dry weather can increase the likelihood of plant damage. Even using pesticides in accordance with the label can result in some phytotoxicity. Applying pesticides within recommended rates and following label instructions for mixing and applying help avoid this problem.

Pesticide resistance—the genetically acquired ability of an organism to tolerate the toxic effects of a pesticide (for example, malathion-resistant Indian mealmoths, atrazine-resistant common lambsquarter, and ALS-resistant ragweed). Resistance develops from overuse of the same pesticide or from overuse of a class of pesticides with a common mode of action (for example, organophosphates or ALS herbicides). Therefore, it is important to use pesticides only when necessary.

Review Questions

Chapter 1: Integrated Pest Management

Write the answers to the following questions and then check your answers with those in the back of the manual.

1. Define integrated pest management.
2. List three control strategies and give an example of each.

3. Define economic threshold.

4. A high-value crop will usually have a high economic threshold.

   A. True

   B. False

5. Field scouting is important because it helps determine pest:

   A. Presence.

   B. Location.

   C. Life stage.

   D. All of the above.

6. When scouting a field, you should sample only from:

   A. Border rows.

   B. One small area of the field.

   C. Randomly picked locations throughout the field.

   D. The edge of the field.

7. List three ways that cultural controls work.

8. Which of the following is an example of a biological control?

   A. Parasitoid

   B. Cover crop

   C. Pesticide

   D. Tillage

9. Host plant resistance is a form of:

   A. Biological control.

   B. Chemical control.

   C. Cultural control.

10. When plant species eliminate other plants by releasing toxic chemicals, it is called:

    A. Phytotoxicity.

    B. Allelopathy.

    C. Sanitation.

    D. Carryover.

11. After the growing season, destroying or removing crop residue can help reduce potential insect and disease problems the following year.

    A. True

    B. False

12. Pesticides are NOT part of an IPM program.

    A. True

    B. False

13. Herbicides that are applied and mixed into the soil before crop planting are called _____ herbicides.

    A. Preemergence

    B. Postemergence

    C. Preplant incorporated

    D. Broadcast

14-18. Match the following scenarios with the type of pesticide application you would perform to combat the problem.

A. Preventive

B. Curative

14. ___ Very weedy cornfield; the corn is knee-high.

15. ___ A neighboring field is infected with a disease and you don't want it in your field.

16. ___ The MSU Crop Advisory Team alerts you to potential pest outbreaks in your area.

17. ___ You apply a fungicide to get rid of a disease.

18. ___ When scouting a field, you find that the potato leafhopper population is above the economic threshold.

19. How are tolerance and pesticide residues related?

20-23. Match the following with their definitions.

A. Predators

B. Biological control

C. Pathogens

D. Parasitoids

20. ___ Typically a fly or tiny wasp that develops inside another insect.

21. ___ Generalist (organisms that eat almost anything).

22. ___Using living organisms to control a pest.

23. ___ Viruses or bacteria.

24-27. Match the following words with their definitions.

A. Pesticide resistance

B. Reentry interval

C. Preharvest interval

D. Phytotoxicity

24. ___ Reduces unnecessary pesticide exposure to workers.

25. ___ Damage to a crop caused by pesticide application.

26. ___ Avoids harvesting pesticide-contaminated crops.

27. ___ Results from the continued use of the same pesticide.

CHAPTER 2

MINIMIZING PESTICIDE IMPACT

LEARNING OBJECTIVES

After completely studying this chapter, you should:

- Understand pesticide labeling.
- Understand the difference between point and non-point source pollution.
- Understand management practices to reduce groundwater contamination.
- Understand how to protect non-target organisms from pesticides.
- Understand how pesticide resistance develops and how to delay or prevent resistance.

STATE AND FEDERAL LAWS

The *Pesticide Applicator Core Training Manual* (E-2195) discusses federal and state laws governing the use and handling of pesticides. These federal laws include the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA), the Occupational Safety and Health Act (OSHA), the Endangered Species Act, and the Worker Protection Standard (WPS). Michigan pesticide laws include the Natural Resources and Environmental Protection Act (Act 451, P.A. 1994, Part 83, Pesticide Control), Regulation 636, Regulation 637, and the Michigan Occupational Safety and Health Act (MIOSHA). Pesticide applicators and technicians should keep up-to-date copies of the laws and review their contents periodically. Copies of these laws can be obtained from Michigan Department of Agriculture (MDA) regional offices. Refer to the core manual (MSU Extension bulletin E-2195) to learn more about these and other laws affecting pesticide use.

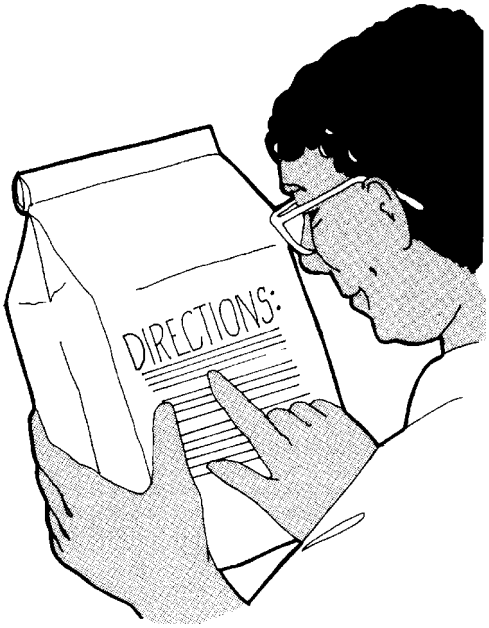
GUIDELINES FOR SELECTION AND USE OF PESTICIDES

The most important law regulating pesticide registration, distribution, sales, and use in the United States is the Federal Insecticide, Fungicide, and Rodenticide Act, or FIFRA. The Environmental Protection Agency (EPA) and the Michigan Department of Agriculture (MDA) administer FIFRA.

Pesticide labels provide use information such as safety precautions, application rates, sites where the pesticide can be applied, and target pests. They contain information to protect the applicator, the environment, and the crop while maximizing pest control. Pesticide labels are legal documents that must be followed. Always read the entire label and all supplemental labeling before using a pesticide. **Supplemental labeling** includes any information you receive from the manufacturer about how to use the product. Supplemental labeling is considered part of the pesticide label and may be supplied at the time of purchase or requested from the dealer. If an applicator applies a pesticide according to a supplemental label, a copy of the supplemental label must be in the applicator's possession at the time of application. Supplemental labels include special local needs labels (24c), emergency exemption labels (section 18), and use information issued by the pesticide manufacturer.

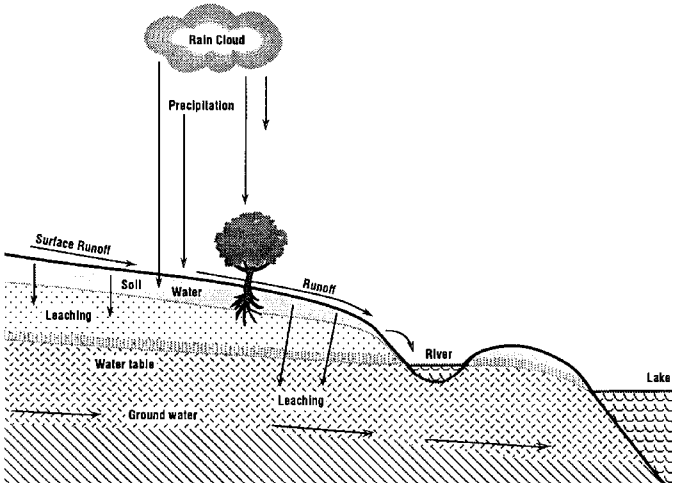
Always:

- Select pesticides labeled for use on your crop.
- Read and understand the label instructions and limitations before each use.
- Follow the application directions on the pesticide label.
- Contact your county MSU Extension office if you have questions or concerns about a particular pesticide.



PROTECTING OUR GROUNDWATER

Groundwater is the water beneath the earth's surface. It is found in the cracks and pores of rocks, and in the spaces between sand grains and other soil particles. Many people living in rural Michigan get their drinking water from wells. It is easy to see why you should be concerned about keeping pesticides out of groundwater.



Groundwater is always moving. Eventually, it reaches the earth's surface at natural places such as lakes, springs, and streams. Sometimes it is pumped to the surface from wells. Every year rain and snow seep into the soil, replenishing the groundwater. The depth at which you first find groundwater is referred to as the **water table**. The water table depth changes during the year, depending on the amount of water added and removed from the ground.

Both **surface water**—visible bodies of water such as lakes, rivers, and oceans—and groundwater are subject to contamination by point and non-point source pollution. When a pollutant enters the water from a specific source, it is called **point source pollution**. For example, a factory that discharges chemicals into a river is a point source. **Non-point source pollution** refers to pollution from a generalized area or weather event, such as land runoff, precipitation, acid rain, or percolation rather than from discharge at a single location.

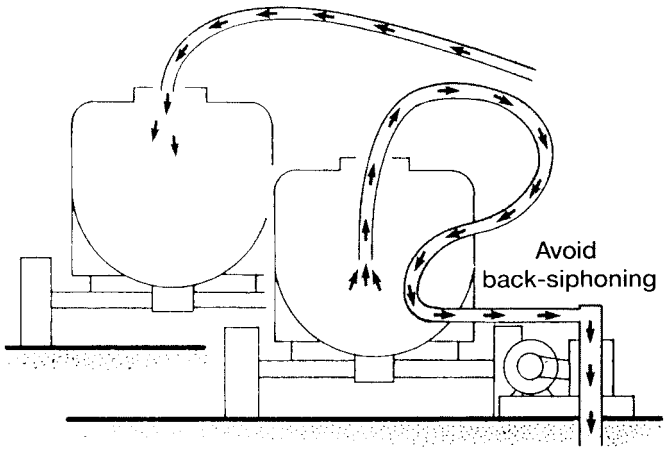
Keeping Pesticides Out of Groundwater and Surface Water

A pesticide that has not become a gas (volatilized), absorbed by plants, bound to soil, or broken down can potentially migrate through the soil to groundwater. Groundwater movement is slow and difficult to predict. Substances entering groundwater in one location may turn up years later somewhere else. A difficulty in dealing with groundwater contaminants is discovering the pollution source when the problem is occurring underground, out of sight. Also, microbial and photodegradation (by sunlight) do not occur deep underground, so pesticides that reach groundwater break down very slowly.

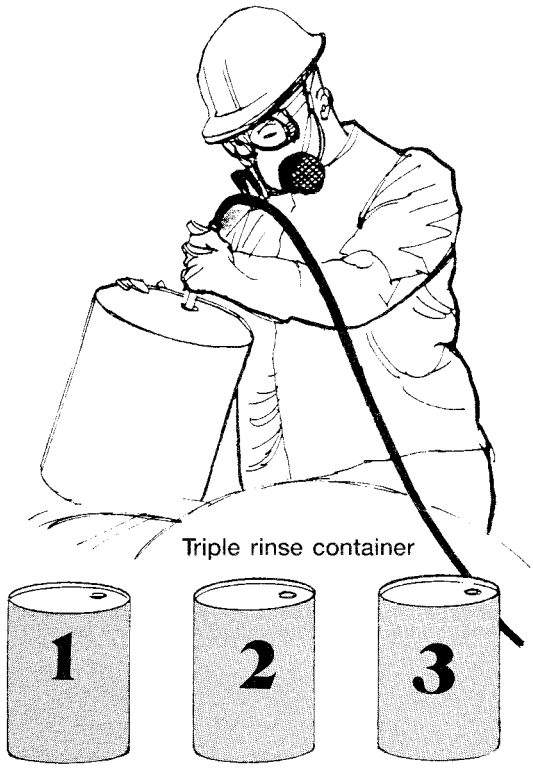
Cleaning contaminated groundwater or surface water is extremely difficult. Following certain practices can reduce the potential for pesticide contamination of groundwater and surface water:

- **Use integrated pest management.** Minimize pesticide use by utilizing other pest management practices to reduce or eliminate pesticide use.
- **Consider the geology of your area** when locating wells, mix/load sites, or equipment washing sites. Be aware of the water table depth and how fast water moves in the geological layers between the soil surface and the groundwater.

- **Select pesticides carefully.** Choose pesticides that are not likely to leach (move downward) in the soil into groundwater or run off into surface water. Pesticides that are very water soluble and not easily bound to soil tend to be the *most likely* to leach. Read pesticide labels carefully, consult the MSU Extension pesticide application guides, and/or seek advice from an MSU specialist or a pesticide dealer to choose the best pesticide for your situation.
- **Follow pesticide label directions.** Container and supplemental pesticide labels are the law. Labels provide crucial information about application rates, timing, and placement of the pesticide. Consult all labels before using the pesticide.
- **Calibrate accurately.** Calibrate equipment carefully and often to avoid over- or underapplication.
- **Measure accurately.** Carefully measure concentrates before placing them into the spray tank. Do not "add a little extra" to ensure that the pesticide will do a better job.
- **Avoid back-siphoning.** Make sure the end of the fill hose remains above the water level in the spray tank at all times. This prevents **back-siphoning** of the pesticide into the water supply. Use an anti-backflow device when siphoning water directly from a well, pond, or stream. Do not leave your spray tank unattended.



- **Consider weather conditions.** If you suspect heavy rain will occur, delay applying pesticides.
- **Mix on an impervious pad.** Mix and load pesticides on an approved impervious mix/load pad where spills can be contained and cleaned up. If mixing in the field, change the location of the mixing area regularly. A portable mix/load pad is required if you fill at the same location ten or more times per year.
- **Dispose of wastes and containers properly.** All pesticide wastes must be disposed of in accordance with local, state, and federal laws. Triple-rinse containers. Pour the rinse water into the spray tank for use in treating the labeled site or crop. After triple rinsing, perforate the container so it cannot be reused. Recycle all metal and plastic triple-rinsed containers. Otherwise, dispose of them in a state-licensed sanitary landfill. Dispose of all paper containers in a sanitary landfill or a municipal waste incinerator. Do not burn used pesticide containers. Burning does not allow for complete combustion of most pesticides, resulting in pesticide movement into the air; it is also a violation of state regulations administered by the Michigan Department of Environmental Quality. Contact your regional MDA office or local county Extension office for more information on pesticide container recycling in your area.



- **Store pesticides safely and away from water sources.** Pesticide storage facilities should be situated away from wells, cisterns, springs, and other water sources. Pesticides must be stored in a locked facility that will protect them from temperature extremes, high humidity, and direct sunlight. The storage facility should be heated, dry, and well ventilated. It should be designed for easy containment and cleanup of pesticide spills and made of materials that will not absorb any pesticide that leaks out of a container. Store only pesticides in such a facility, and always store them in their original containers.

PROTECTING NON-TARGET ORGANISMS

Insecticides can kill **bees and other pollinating insects**. To reduce the chance of bee poisoning:

- **Select the least hazardous pesticide formulation for bees**. Dusts are more hazardous to bees than sprays. Wettable powders are more hazardous than emulsifiable concentrates (EC) or water-soluble formulations. Microencapsulated pesticides are extremely dangerous to bees because the very small capsules can be carried back to the hive. Granular insecticides are generally the least hazardous to bees.

- **Do not apply pesticides that are toxic to bees if the site contains a blooming crop or weed.** Remove the blooms by mowing before spraying.
- **Minimize spray drift** by selecting appropriate nozzles, adding an adjuvant, or postponing the application to a less windy time.
- **Time pesticide applications carefully**. Evening applications are less hazardous than early morning ones; both are safer than midday applications.
- **Do not treat near beehives.** Bees may need to be moved or covered before you use pesticides near hives.

The best way to avoid injury to beneficial insects and microorganisms is to minimize the use of pesticides. Use selective pesticides when possible. Apply pesticides only when necessary and as part of an integrated pest management program.

Pesticides can also be harmful to **vertebrates** such as fish and wildlife. Fish kills may result when a pesticide (usually an insecticide) pollutes water or changes the pH of the water. Pesticides may enter water via drift, surface runoff, soil erosion, and leaching.

Pesticides may result in bird kills if birds ingest granules, baits, or treated seed; are exposed directly to the spray; drink and use contaminated water; or feed on pesticide-contaminated prey.

Endangered and threatened species are of special concern. Under the federal Endangered Species Act, every pesticide posing a threat to an endangered or threatened species or to its habitat must have a warning statement on the label. The warning provides instructions on how to safeguard the species when using the pesticide within its habitat.

POTENTIAL FOR PESTICIDE RESISTANCE

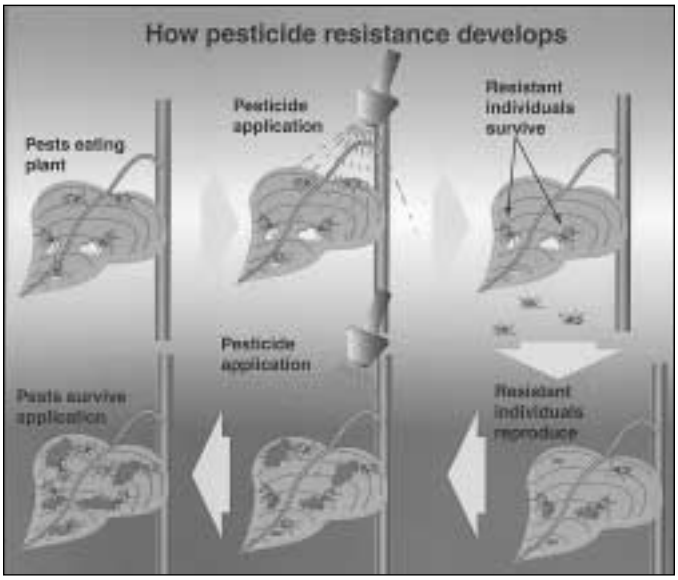
Pesticide resistance is a measurement of a pest's ability to tolerate the toxic effects of a particular pesticide. As the number of resistant individuals increases in a pest population, the original application rate or spray frequency no longer provides adequate control.

The Development of Resistance

Repeated applications of the same pesticide or of pesticides with a common mode of action give a pest population a chance to develop resistance. **Resistance** is an individual's (weed, crop, insect, etc.) ability to survive a specific pesticide application. There are four mechanisms of resistance. Resistant individuals:

1. Change the site of action so that the pesticide no longer functions.
2. Metabolize the pesticide. **Metabolism** is a biochemical process that modifies the pesticide to less toxic compounds.
3. Remove the pesticide from the site of action.
4. Break down (detoxify) the pesticide.

Resistant individuals survive when the pesticide is applied, and their offspring inherit the pesticide resistance. With each generation, more individuals in the population are resistant. Because the pesticide kills most of the non-resistant individuals, the resistant organisms make up an increasingly larger percentage of the surviving pest population. With each use of the pesticide, this percentage increases until the chemical is no longer effective against the pest.



In most cases, pests that are resistant to one pesticide will show resistance to chemically related pesticides. This is called **cross-resistance**. Cross-resistance occurs because closely related pesticides kill pests in the same way—for example, all organophosphate insecticides kill by inhibiting the same enzyme in the nervous system, cholinesterase. If a pest can resist the toxic action of one

pesticide, it can often survive applications of other pesticides that kill same way.

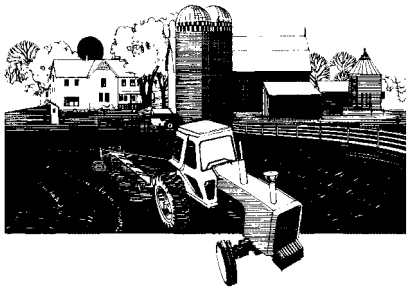
Resistance Management

Resistance management attempts to prevent, delay, or reverse the development of resistance. A resistance management program includes:

- **Using integrated pest management.** Combine cultural, mechanical, biological, and chemical control measures into a practical pest control program. For example, crop rotation can reduce the buildup of pests in a particular crop, reducing the number of pesticide applications needed. This reduces the advantage that resistant individuals have over non-resistant individuals and delays or prevents the buildup of resistance in a population.
- **Using pesticides from different chemical families with different modes of action.** Try to do this whether you apply pesticides against a pest once a year or several times within a treatment season. Generally, pests resistant to the first pesticide will be killed by the second.
- **Using pesticides only when needed, and using only as much as necessary.**

NOTIFYING NEIGHBORS

Good public relations are extremely important when applying pesticides. It is the joint responsibility of landowner and applicator to see that neighboring landowners are not subjected to acts of trespass or exposed to spray drift. As a matter of courtesy, it is a good idea to inform adjacent landowners, neighbors, and beekeepers in advance of any large-scale pesticide application.



If off-target pesticide drift is expected, Michigan Regulation 637 requires a pesticide applicator to have a drift management plan. A drift management plan should contain:

- A map of all areas where pesticide applications occur.
- A list of pesticide-sensitive sites located near an application area—for example, schools, day care facilities, or sensitive crops.
- Pesticide label and mandated restrictions that relate to setback provisions from sensitive areas.
- Information for persons in sensitive areas regarding the type of pesticide used, the method of application, and the applicator's plan to minimize pesticide drift.

A drift management plan should be used by private and commercial applicators as a communication tool to minimize adverse effects of off-target drift. For more information on drift management plans, contact the Michigan Department of Agriculture.

CHAPTER 2

Review Questions

Chapter 2: Minimizing Pesticide Impact

Write the answers to the following questions and then check your answers with those in the back of the manual.

1. A pesticide label is a legally binding document.
   A. True
   B. False

2. What is supplemental labeling? Give an example.

3. A certified pesticide applicator may apply a pesticide labeled for use on alfalfa to soybeans only if:
   A. The same pest is present on both crops.
   B. Use for soybeans is also on the pesticide label.
   C. A lower rate is applied to the soybeans.
   D. The pest density is above the economic threshold.

4. Which of the following is NOT true about groundwater?
   A. It is always moving.
   B. It is measured by the water table.
   C. It is found at the earth's surface.
   D. It is used as drinking water.

5. When applying a pesticide according to the instructions on a supplemental label, you should have
   A. A Michigan Department of Agriculture official with you.
   B. The dealer's phone number with you.
   C. A copy of the Michigan pesticide laws with you.
   D. The label with you.

6. The part of the government that regulates pesticides in the United States is the:
   A. Environmental Protection Agency (EPA).
   B. Food and Drug Administration (FDA).
   C. U.S. Department of Agriculture (USDA).
   D. Occupational Safety and Health Administration (OSHA).

7. The least hazardous pesticide formulation for bees and other pollinating insects is:
   A. Emulsifiable concentrates.
   B. Granular.
   C. Wettable powders.
   D. Dusts.

8. The water table depth changes:
   A. In the summer.
   B. In the winter.
   C. Never.
   D. Throughout the year.

9. Rain and melting snow do NOT affect the water table.
   A. True
   B. False

10. Non-point source pollution is generally easier to trace back to the origin than point source pollution.
    A. True
    B. False

11. List five ways you can reduce the risk of pesticides contaminating groundwater.

12. Which of the following is true about back-siphoning?

    A. It does not occur with an IPM program.
    B. It helps minimize pesticide drift.
    C. It can lead to contamination of water.
    D. It occurs when pesticides volatilize.

13. Which of the following is a proper method of disposing of an empty pesticide container?

    A. Burn it.
    B. Rinse and dispose in a licensed landfill.
    C. Use it to hold other pesticides.
    D. Bring to your local MDA office.

14. The impact of pesticides on bees and other pollinating insects can be reduced by applying:

    A. Pesticides under favorable weather conditions.
    B. When plants are in bloom.
    C. Microencapsulated pesticides.
    D. Broad-spectrum pesticides.

15. Pesticides are NOT harmful to fish and birds.

    A. True.
    B. False.

16. The ability of a pest to detoxify a pesticide and survive is:

    A. Resistance.
    B. Phytotoxicity.
    C. Pollution.
    D. Pesticide drift.

17. A resistance management program will _____ the development of pesticide resistance.

    A. speed up
    B. slow down

18. The ability of a pest to develop resistance to similar pesticides is called:

    A. Mechanical control
    B. Cross-resistance.
    C. Cholinesterase.
    D. Resistance management.

19. In Michigan, a drift management plan is required if off-target pesticide drift is likely to occur.

    A. True.
    B. False.

20. List four items to include in a drift management plan.

CHAPTER 3

APPLICATION EQUIPMENT

LEARNING OBJECTIVES

After completely studying this chapter, you should:

- Know the various pesticide application methods and the factors that influence your choice of the appropriate method.
- Know special application methods that are used for field crop weed control and when and how they are applied.
- Know the various sprayer components, how they operate, and what the desirable features are.
- Know the various sprayer types, how they operate, and desirable features.
- Understand proper operation and maintenance of sprayers before, during, and after spraying.
- Know the various types of granular applicators and application methods, when they are applied, and what they consist of.

METHODS OF APPLICATION

The method you choose to apply a pesticide will depend on the nature and habits of the target pest, the site, the pesticide, available application equipment, and the cost and efficiency of alternative methods. Some common application methods are described below.

Broadcast application is the uniform application of a pesticide to an entire area.

A **directed-spray application** targets pests in a specific area in an effort to minimize pesticide contact with the crop or beneficial insects.

Foliar application directs pesticide to the leafy portions of a plant.

Spot treatment is application of a pesticide to small, discrete areas.

Soil application places pesticide directly on or in the soil rather than on a growing plant.

Soil incorporation is the use of tillage equipment to mix the pesticide with the soil.

Soil injection is application of a pesticide beneath the soil surface.

TYPES OF SPRAYERS

When selecting a sprayer, be certain that it will deliver the proper rate of pesticide uniformly over the target area. Most pesticide applications in field crops are done with a hydraulic sprayer at either high or low pressures.

Hydraulic Sprayers

Water is most often used with hydraulic spraying equipment as the means of carrying pesticide to the target area. The pesticide is mixed with enough water to obtain the desired application rate at a specific pressure and travel speed. The spray mixture flows through the spraying system under pressure and is released through one or more nozzles onto the target area.

Low-pressure Sprayers

Low-pressure sprayers normally deliver low to moderate volumes at low pressure–15 to 100 pounds of pressure per square inch (psi). The spray mixture is applied through a boom equipped with nozzles. The boom usually is mounted on a tractor, truck, or trailer, or the nozzle(s) can be attached to a hand-held boom.

Low-pressure sprayers do not deliver sufficient volume to penetrate dense foliage. They are most useful in distributing dilute pesticide over large areas.

High-pressure Sprayers

High-pressure sprayers deliver large volumes at high pressure. They are similar to low-pressure sprayers except that they deliver up to 50 gallons of spray per minute at pressures up to 800 psi. A boom delivers 200 to 600 gallons per acre.

High-pressure sprayers provide thorough coverage and can penetrate dense foliage; however, these sprayers produce large numbers of small spray droplets that can drift. These sprayers can provide low-pressure flow when fitted with proper pressure regulators.

PARTS OF A SPRAYER

To properly select, maintain, and operate your sprayer, you need to know its parts. The major components of a sprayer are tank, pump, agitator, flow control, and nozzles.

Sprayer tank, wand, pump and gauge.

Tanks

Suitable materials for spray tanks include stainless steel, polyethylene plastic, and fiberglass. Spray tanks made of aluminum and galvanized and stainless steel are easily corroded by some pesticides and liquid fertilizers. The tank cover should form a watertight seal when closed to minimize spills. All tanks should have a drain plug at their lowest point and shut-off valves so that any liquid in the tank can be held without leaking if the pump, strainers, or other parts of the system need to be serviced.

Tank capacity markings must be accurate so that you can add the correct amount of water. A clear plastic tube (sight gauge) is mounted on metal tanks.

Agitators

Agitation is required to combine the components of the spray mixture uniformly and, for some formulations, to keep the pesticide in suspension. If agitation is inadequate, the application rate of the pesticide may vary as the tank is emptied. The two common types of agitation are hydraulic and mechanical.

The quantity of flow required for agitation depends on the chemical used. Little agitation is needed for solutions and emulsions, but intense agitation is required for wettable powders. For jet agitators, a flow of 6 gallons per minute for each 100 gallons of tank capacity is adequate. The jet should be submerged to prevent foaming. Wettable powder suspensions can wear the inside of the tank if the jet stream passes through less than 12 inches of liquid before hitting the tank wall.

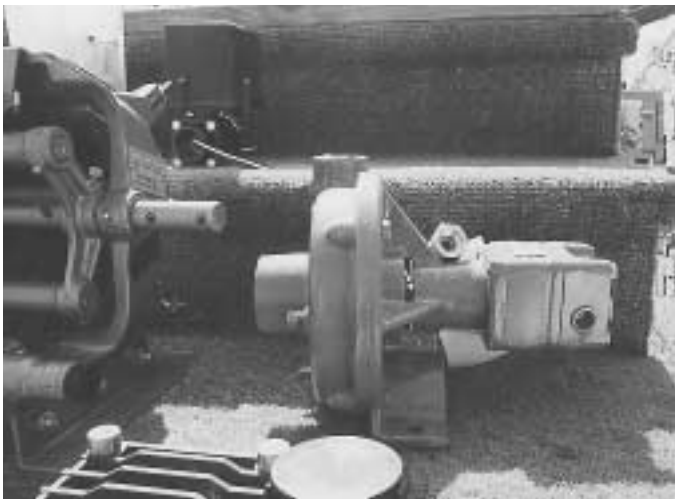
A mechanical agitator consists of a shaft with paddles and is located near the bottom of the tank. The shaft is driven by an electric motor or some other device powered by the tractor. This system is more costly than jet agitation. Mechanical agitators should operate at 100 to 200 revolutions per minute (rpm). Foaming will result at higher speeds.

Pumps

The pump must deliver the necessary flow to all nozzles at the desired pressure to ensure uniform distribution. Pump flow capacity should be 20 percent greater than the largest flow required by the nozzles.

When selecting a pump, consider resistance to corrosive damage from pesticides, ease of priming, and power source availability. The materials in the pump housing and seals should be resistant to chemicals, including organic solvents.

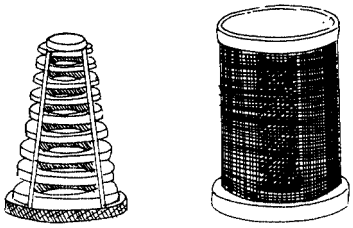
Pesticide sprayers commonly use roller, piston, diaphragm, and centrifugal pumps. Each has unique characteristics that make it well adapted for particular situations. Choose a pump that best fits your pesticide application program.



Centrifugal Pump.

Strainers

Proper filtering of the spray mixture not only protects the working parts of the spray system but also avoids misapplication due to nozzle tip clogging. Three types of strainers commonly used on sprayers are tank filler strainers, line strainers, and nozzle strainers. As the mixture moves through the system, strainer openings should be progressively smaller. Strainer mesh size is determined by the number of openings per linear inch; a high strainer size number indicates smaller openings. Strainers need to be checked for clogs and rinsed frequently.



Strainers.

Hoses

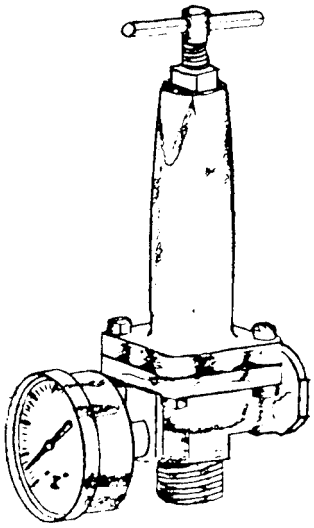
Use synthetic rubber or plastic hoses that have a burst strength greater than peak operating pressures, resist oil and solvents present in pesticides, and are weather resistant.

Sprayer lines must be properly sized for the system. The suction line, often the cause of pressure problems, must be airtight, non-collapsible, and as short as possible, and have an inside diameter as large as the pump intake.

Pressure Regulators

A pressure regulator is one of the most important parts of a sprayer. It controls the pressure and therefore the quantity of spray material delivered by the nozzles. It protects pump seals, hoses, and other sprayer parts from damage due to excessive pressure, and it bypasses excess spray material back to the tank.

There are two types of pressure regulators–simple relief valves and pressure unloaders. Relief valves are simple bypass valves that require the pump and engine to keep working just as though you were spraying. Pressure unloaders maintain working pressure on the discharge end of the system but move the overflow back into the tank at lower pressure, thus reducing strain on the engine and the pump.

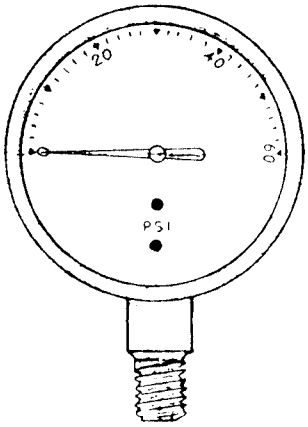


Pressure regulator.

Be certain that the flow capacity of the pressure regulator matches that of the pump being used.

Pressure Gauge

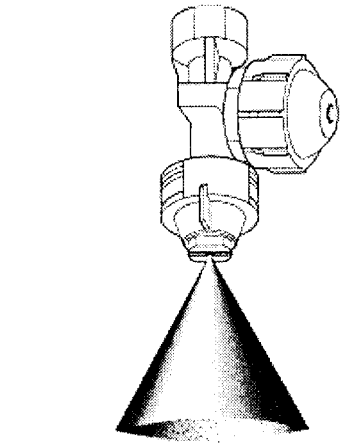
A pressure gauge is essential to every sprayer system to correctly indicate the pressure at the nozzle. Pressure directly affects the application rate and spray distribution. Pressure gauges often wear out because they become clogged with solid particles of spray material. A glycerine-loaded diaphragm gauge is more expensive but will last indefinitely.



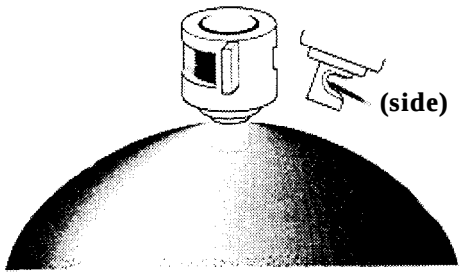
Pressure guage.

Nozzles

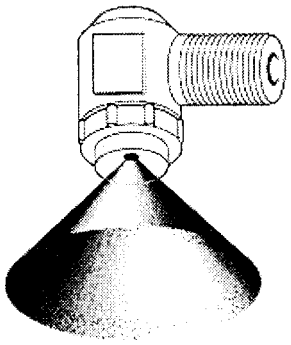
Nozzles are important to control the volume of pesticide applied, the uniformity of application, the completeness of coverage, and the degree of drift. Many types of nozzles are available, each one designed for a specific type of application. Regular flat-fan, flood, and whirl chamber nozzles are preferred for weed control. For minimum drift, flood and raindrop nozzles are preferable because they produce large droplets.



Regular Flat Fan



Flooding Flat Fan (front



RA-raindrop

Types of nozzles.

Regular Flat-fan Nozzle

Regular flat-fan nozzles are designed for broadcast applications and are sometimes used on high-clearance and pickup sprayers. They are typically used for foliar applications and require a 30 to 50 percent pattern overlap to obtain uniform coverage. Flat-fan nozzles are recommended for herbicides and insecticides where foliage penetration and complete coverage are not necessary.

Regular flat-fan nozzles produce a narrow oval pattern and medium droplets at pressures of 15 to 20 psi. Drift potential increases at pressures above 30 psi.

Flooding Flat-fan Nozzle

Flooding flat-fans are the most commonly used nozzles. They produce a wide-angle pattern that varies with pressure. At high pressure, the pattern is heavier in the center and tapers off toward the edges; at low pressures, they produce a uniform pattern.

Pressure also affects droplet size. Flooding flat-fan nozzles produce large spray droplets at low pressure and small droplets at high pressure. To control drift, flooding nozzles should be operated at between 8 and 25 psi.

Hollow-cone whirl chamber nozzle

The hollow-cone nozzle is used primarily to penetrate foliage for effective pest control when drift is not a concern. These nozzles produce small droplets at pressures of 40 to 80 psi that penetrate plant canopies and cover the undersides of leaves more effectively than spray from other nozzles.

Whirl chamber nozzles have two pieces. The first part is the whirl chamber, which squirts the material as it moves through the second piece, a disk. This results in a circular hollow-cone spray pattern.

Raindrop Nozzle

Raindrop nozzles are designed to reduce drift. This nozzle produces large droplets in a hollow-cone pattern when operated between 20 and 50 psi. The large droplets aid in drift control but may result in poor coverage by some foliar pesticides.

Nozzles are available in a variety of materials. Brass nozzles are inexpensive but wear rapidly. Stainless steel, nylon, and other plastic nozzles are wear resistant when used with corrosive or abrasive materials. Nozzles made of hardened stainless steel are the most wear resistant and expensive.

OPERATION AND MAINTENANCE OF SPRAYERS

Proper operation and maintenance of spray equipment will lead to safe and effective pest control, significantly reduced repair costs, and prolonged life of the sprayer.

Before Spraying

At the beginning of each spraying season, fill the tank with water and pressurize the system to be sure all the parts are working and there are no drips or leaks. All nozzles should be of the same type, size, and fan angle. If

using nozzle strainers, make sure the check valves are working properly. Functioning check valves prevent dripping when flow to the nozzle drops below a specific pressure. Measure the distance between the nozzle tip and the target, and adjust the boom accordingly. In broadcast applications, nozzle height affects the uniformity of the spray pattern.

Fill the tank with water that does not have silt or sand in it. Keep the tank level when filling to make sure the quantity in the tank is correctly indicated.

Calibrate the sprayer before using. (Calibration is discussed in Chapter 4 of this manual.)

During Spraying

Frequently check the pressure gauge to make sure the sprayer is operating at the same pressure and speed used during calibration. Operate the sprayer at speeds appropriate for the conditions. Bouncing and swaying booms can cause application rates to vary. Periodically check hoses and fittings for leaks, and check nozzles for unusual patterns. If you must make emergency repairs or adjustments in the field, wear the protective clothing listed on the label as well as chemical-proof gloves.

After Spraying

Always flush the spray system with water after each use. Apply this rinse water to sites for which the pesticide is labeled. Clean the inside and outside of the sprayer thoroughly before switching to another pesticide and before doing any maintenance or repair work. All parts exposed to a pesticide will normally have some residue, including sprayer pumps, tanks, hoses, and boom ends.

GRANULAR APPLICATIONS

Granular applicators are designed primarily for soil applications and are available in various styles and sizes. Drop-through spreaders and rotary spreaders are the most common types of applications.

Granular applicators normally consist of a hopper for the pesticide, a mechanical-type agitator at the base of the hopper to provide efficient and continuous feeding, and some type of metering device, usually a slit-type gate, to regulate the flow of the granules.

Drop-through Spreaders

Drop-through spreaders are available in many widths. An adjustable sliding gate opens holes in the bottom of the hopper and the granules flow out by gravity feed. Normally, a revolving agitator is activated when the spreader is in motion to assure uniform dispensing.

Rotary Spreaders

Rotary spreaders distribute the granules to the front and sides of the spreader, usually by means of a spinning disk or fan. Heavy granules are thrown farther than lighter ones. A 6- to 8-foot swath width is common. Both power- and hand-driven rotary spreaders are available.

FIELD OPERATIONS

Pest control with pesticides relies on uniform application of the correct amount of product at the most efficient time. Clogged or worn nozzles, overlapping, and deviations in swath width can double applications or create skips in the treated area.

Dripping nozzles can cause crop damage during turns or when the sprayer is stopped for any reason. Use a positive shutoff, such as a high-capacity diaphragm check valve, to avoid dripping nozzles. Hydraulic and air-activated shutoff systems are more reliable but much more expensive.

GLOBAL POSITIONING SYSTEM (GPS) AND GEOGRAPHICAL INFORMATION SYSTEM (GIS)

Global positioning system (GPS) and geographical information system (GIS) technology has helped increase the accuracy of pesticide applications. This technology combines a tracking and guidance system with precise field mapping. Global positioning systems are based on the triangulation of worldwide satellite signals to determine exact field location. Geographic information systems are computer systems that interpret, manipulate, and display GPS information about a specific location. For example, a grower using a global position system can record the exact location of weedbeds in a field. A geographic information system can interpret this information and produce a map of the weed bed locations. This map can be used to apply pesticides directly to the weed beds the following year.

Geographic information systems can also be linked directly to application equipment and used to turn spray nozzles on and off. This results in pesticide applications only where necessary. Global positioning and geographical information systems are more often used with herbicide and fungicide applications.

CHAPTER 3

Review Questions

Chapter 3: Application Equipment

Write the answers to the following questions and then check your answers with those in the back of the manual.

1. Which of the following methods of application mixes the pesticide into the soil?
   A. Soil treatment
   B. Soil application
   C. Soil fumigation
   D. Soil incorporation

2. What are some of the factors that influence the choice of pesticide application method?

3. What is one reason to use a directed-spray pesticide application?
   A. To minimize contact with beneficial insects.
   B. To get an evenly distributed application.
   C. To avoid back-siphoning.
   D. All of the above.

4. Pesticides can corrode certain materials from which spray tanks are made.
   A. True
   B. False

5. A spray tank should have:
   A. An opening for filling.
   B. A shutoff before the pump.
   C. A drain plug at the lowest point.
   D. All of the above.

6. To compensate for pump wear, pump flow capacity should _____ the largest flow required by the nozzles and hydraulic agitation.
   A. Be less than
   B. Be equal to
   C. Be greater than
   D. Not affect

7. All spray pumps are resistant to the corrosive effects of pesticides.
   A. True
   B. False

8. Which of the following formulations requires the most agitation?
   A. Wettable powders
   B. Solutions
   C. Emulsions
   D. Liquids

9. Hydraulic agitation is accomplished by a shaft with paddles in the spray tank.
   A. True
   B. False

10. With paddle agitation, foaming can result if the shaft motor is operated:
    A. Too slow.
    B. Too fast.
    C. Too long.
    D. Too little.

11. With hydraulic agitation, foaming can result if the jet is:

    A. Not operating.
    B. Above the liquid level in the tank.
    C. Below the liquid level in the tank.
    D. All of the above.

12. As liquid moves from the spray tank to the nozzle, the strainer mesh should:

    A. Remain the same.
    B. Become larger.
    C. Become smaller.
    D. Not matter.

13. Strainers within the spray system are cleaned automatically by the movement of the spray solution.

    A. True
    B. False

14. The burst strength of spray system hoses should be greater than the:

    A. Peak operating pressure.
    B. Volume of spray delivered.
    C. Length of the hose.
    D. Temperature during the application.

15. What does the pressure regulator do?

16. Relief valves and pressure unloaders are two types of:

    A. Pressure gauges.
    B. Nozzles.
    C. Pressure regulators.
    D. Hose fittings.

17. Nozzle types are specific to the types of applications.

    A. True
    B. False

18. Low-pressure sprayers and high-pressure sprayers are most efficient if they have the same type of pump.

    A. True
    B. False

19. Low-pressure sprayers are very useful for:

    A. Penetrating dense foliage.
    B. Delivering dilute pesticide over large areas.
    C. Spot treatment.
    D. All of the above.

20. High-pressure sprayers can:

    A. Provide high volume at high pressure.
    B. Penetrate dense foliage.
    C. Increase spray drift.
    D. All of the above.

21. What are the first two tasks when readying sprayers for the new season?

22. If a sprayer breaks down, it is NOT necessary to wear personal protective equipment while doing repairs.

    A. True
    B. False

23. After the inside of the spray tank has been rinsed with water, the water should be:

    A. Sprayed on any site as long as it has plant material growing on it.
    B. Sprayed on any bare soil.
    C. Sprayed on a site that appears on the pesticide label.
    D. Stored.

24. Granular applicators are designed primarily for:

    A. Foliar application.
    B. Soil application.
    C. Spot application.
    D. Basal application.

25. How can global positioning systems and geographical information systems aid a pesticide applicator?

CHAPTER 4

CALIBRATION

LEARNING OBJECTIVES

After completely studying this chapter, you should:

- Understand the purpose of calibration and why it is an essential process.
- Know the basic tools needed to calibrate sprayers and the variables that determine spray rate.
- Be able to check for and calculate nozzle output and know the guideline for determining when nozzles are worn out.
- Know what factors affect spray pattern uniformity and how to check for it.
- Understand how to calibrate a sprayer for ***broadcast application***.
- Be able to calculate how much pesticide to add to the spray tank for broadcast application.
- Know how to properly calibrate a hand sprayer on a per acre basis and for a ***band application***.
- Know how to calibrate granular applicators, both drop-through spreaders and rotary spreaders.

INTRODUCTION

The purpose of **calibration** is to ensure that your equipment delivers the correct amount of pesticide uniformly over the target area. Calibration is the step in pesticide application that is most often neglected and misunderstood. Because virtually every sprayer is a unique combination of pumps, nozzles, and other equipment, calibration is an essential process for an applicator to learn.

For proper calibration, you will need a few basic tools, including a stopwatch, a collection container graduated in ounces, a tape measure, and flags or stakes for marking. Unless your sprayer is new, it will contain a certain amount of pesticide residue; therefore, a pair of chemical-proof gloves is also recommended. Additionally, a pocket calculator will help with calculations.

In this chapter, we provide formulas that are designed to make calibration easier for you. Some of these formulas have constants–i.e., numbers that remain the same whenever you use that formula. To make calibrations easier for you, we provide you with the constants.

CALIBRATION OF SPRAYERS

Calibrating a sprayer ensures that the sprayer is delivering the intended volume of spray mixture to the target area. You must determine each of the following:

- The amount of product the sprayer delivers per acre.
- The number of acres you can spray per tank.
- The recommended rate of pesticide application.
- The amount of pesticide to add to the spray tank.

Variables That Determine the Spray Rate

Two major variables affect the amount of spray mixture applied per acre (most commonly expressed in gallons per acre): the *nozzle flow rate* and the *ground speed* of the sprayer. You must understand the effect that each of these variables has on sprayer output to calibrate and operate your sprayer properly.

Nozzle Flow Rate

The flow rate through a nozzle varies with the nozzle pressure and the size of the nozzle tip. Increasing the pressure or using a nozzle tip with a larger opening will increase the flow rate (gallons per acre).

Increasing pressure will NOT give you a proportional increase in flow rate. For example, doubling the pressure

will not double the flow rate–you must increase the pressure fourfold to double the flow rate.

Sprayer pressure (speed constant)	Sprayer output (gallons per acre)
10 psi	10
40 psi	20
160 psi	40

Pressure cannot be used to make major changes in spray rate, but it can be used to make minor changes. Keep in mind that operating pressure must be maintained within the recommended range for each nozzle type to obtain a uniform spray pattern and minimize drift.

The easiest and most effective way to make a large change in flow rate is to change the size of the nozzle tips. Depending on operating pressure, the speed of the sprayer, and nozzle spacing, small changes in nozzle size can significantly change sprayer output per acre. Use nozzle manufacturers' catalogs to select the proper tip size.

Ground Speed of the Sprayer

Provided the same throttle setting is used, as speed increases, the amount of spray applied per unit area decreases at an equivalent rate. For example, doubling the ground speed of a sprayer will reduce the amount of spray applied by one-half.

Sprayer speed (under constant pressure)	Sprayer output (gallons per acre)
1 mph	40
2 mph	20
3 mph	13.3
4 mph	10

To determine the new output after changing speed:

$$\text{New output} = \frac{\text{old output x old speed}}{\text{new speed}}$$

Some low-pressure sprayers are equipped with control systems that maintain a constant application rate over a range of travel speeds, provided the same gear setting is used. Pressure is automatically changed to vary the nozzle flow rate in proportion to changes in ground speed. Even so, do your calibration at a set ground speed. In the field, travel speed must be kept within certain limits to keep the nozzle pressure within the recommended range.

Precalibration Check of Nozzle Output

After making sure the system is clean, fill the tank approximately half full with water. Fasten a graduated container under each nozzle and operate the sprayer for one minute at a pressure within the recommended pressure range. Check to see that the flow rate from each nozzle is approximately the same; replace or clean any nozzle whose output differs by more than 5 percent from the average for all of the nozzles and again check the flow rates.

For example, the following flow rates are obtained for six nozzles:

Nozzle	Output (ounces per minute)
1	40.0
2	43.0
3	39.5
4	40.5
5	37.5
6	39.5
	Total 240.0 ounces

The average nozzle output is 40 ounces (240 ÷ 6).

Five percent of 40 ounces (40 x 0.05) is 2 ounces. Any nozzle whose output differs from 40 ounces by more than 2 ounces should be cleaned or replaced; that is, any nozzle whose output is greater than 42 or less than 38. Therefore, nozzle #5 should either be cleaned or replaced. The flow rate of nozzle #2 is too high. This indicates that the nozzle is worn and should be replaced.

When the average nozzle output varies by more than 10 percent from the manufacturer's specifications, the nozzles are worn enough to justify the purchase of a new set. This is particularly important when using flat-fan or flood nozzles because proper spray overlap becomes difficult to maintain with worn nozzles.

Spray Pattern Uniformity

A uniform spray pattern is crucial for an effective pesticide application. It's not enough to apply a pesticide only in its correct amount–you also must apply it uniformly over the target area. The effects of non-uniform application are most obvious when herbicide bands overlap and streaking results. Spray pattern uniformity is affected by boom height, spacing and alignment of nozzles on the boom, condition of nozzles (worn, damaged), and operating pressure. Check that all nozzles are of the same type. Also, a frequent cause of poor spray patterns is using nozzles with different spray angles on the same boom.

To check the uniformity of the spray pattern, adjust the boom height for the spray angle and nozzle spacing being used. Align flat-fan nozzles at a slight angle to the boom. Using water, operate the sprayer at the desired speed and pressure on clean, dry pavement or on another smooth surface. Observe the spray pattern as the water evaporates. Clean or replace nozzle tips that produce a poor spray pattern; if necessary, readjust boom height and recheck the spray pattern. If you replace any nozzles, recheck the flow rates.

Broadcast Sprayer Calibration

There are a number of equally effective calibration methods that vary in their basic approach and degree of difficulty. For the purposes of this manual, we have chosen a simple method that will allow you to calibrate quickly.

1. Fill the sprayer tank approximately half full with water.
2. Determine the nozzle spacing or band width in inches and stake out the appropriate distance in the field according to the following table:

Broadcast nozzle spacing or band width (inches)	Travel distance (feet)
8	510
10	408
12	340
14	291
16	255
18	227
20	204
22	185
24	170
26	157

For other nozzle spacings or band widths, determine the appropriate travel distance using the following formula:

$$\text{Travel distance (feet)} = \frac{4{,}080}{\text{nozzle spacing or band width (inches)}}$$

In this formula, 4,080 is a constant.

For example, if your nozzle spacing is 38 inches:

$$\text{Travel distance} = \frac{4080 = 107 \text{ feet}}{38}$$

Measuring the appropriate travel distance is a critical step in calibration. To determine what volume your sprayer is delivering per acre, you must relate the average nozzle output to a smaller unit area of land. You could determine the volume output by physically spraying an entire acre, but this would be very time consuming. Therefore, we use a fraction of an acre.

3. With the sprayer turned off, drive the distance using the exact throttle setting and gear you plan to use during spraying. Be sure to *note the throttle setting and gear;* don't rely on a speedometer. Start the spray rig about 25 feet before the staked area so that you will be at typical field speed at the beginning of the measured distance. *Record your travel time in seconds.*
4. Adjust the pressure to the desired setting. Use slightly higher pressure when you use nozzle check valves and nozzle strainers.
5. With the sprayer stationary, collect and record the output (in ounces) from at least four nozzles for the travel time recorded in step 3. Because we already determined that the output of all nozzles is within 5 percent of one another in the precalibration check, it is not necessary to collect output from all nozzles.
6. *Determine the average nozzle output in ounces.*
7. The spray rate in gallons per acre is equal to the average nozzle output in ounces. For example, if the average nozzle output for the recorded travel time is 20 ounces, the spray rate is 20 gallons per acre.
8. If the spray rate is not reasonable for your particular spraying job, you can change output by one of three methods: adjust pressure, change speed, or replace nozzle tips. If only a minor change in output is needed, simply make an adjustment in pressure and determine the new average nozzle output. (Remember that operating pressure must be kept within the recommended range for the nozzle type so that the spray pattern is not distorted.) If a large change in output is necessary, make a change in travel speed. However, you must drive the designated field distance and determine the new travel time before calculating the average nozzle output. If it is impossible to obtain the desired output at an appropriate pressure and ground speed, you will need to change nozzle tips; in this case, you must repeat the precalibration check of nozzle output.

The sprayer is now calibrated. When operated at the designated speed and pressure, it should deliver the desired spray volume. You should occasionally remeasure output to determine if changes in flow rate occurred as a result of nozzle wear or other variations. If you continue to use the same travel speed used during initial calibration, it will take only a few minutes to recheck your sprayer's output.

Example: You want to make a postemergence broadcast application of a herbicide at a spray volume of 20 to 30 gallons per acre using regular flat-fan nozzles spaced 40 inches apart on the boom:

1. Fill the sprayer tank approximately half full with water.
2. The appropriate travel distance for 40-inch nozzle spacing is 102 feet; measure and mark this distance in the field.
3. Using the throttle setting and gear you plan to use during spraying, you find that it takes 14 seconds to drive 102 feet.
4. Adjust the pressure to the desired setting within the recommended pressure range of 15 to 30 psi for regular flat-fan nozzles; your chosen setting is 25 psi.
5. With the sprayer stationary, you collect the following outputs from four nozzles in 14 seconds:

Nozzle	Output (ounces per 14 seconds)
1	15.5
2	16
3	15.5
4	16
	Total = 63 ounces

6. The average output of the nozzles for 14 seconds is:

$$\frac{63 \text{ ounces}}{4 \text{ nozzles}} = 16 \text{ ounces}$$

7. The spray rate, therefore, is equal to 16 gallons per acre.
8. The spray rate is lower than the recommended range of 20 to 30 gallons per acre stated on the label. The major change in output required should not be attempted by increasing pressure. You'll need to either decrease travel speed (in which case you'll also need to determine the new travel time) or increase nozzle tip size. Then determine the new average output.

Amount of Pesticide to Add to the Tank

Your next step is to determine the amount of pesticide to add to the spray tank. To do so, you need to know:

- The recommended rate.
- The capacity of the spray tank.
- The calibrated output of the sprayer.

You just learned how to determine the output of your sprayer.

The recommended rate is determined from the label. Rates are expressed either as the amount of pesticide product applied per acre (or area) or as the amount to mix with a certain volume of water (or other carrier).

Example: Broadcast application. Pesticide A is recommended as a broadcast application at a rate of 2 quarts per acre. Your sprayer has a 200-gallon tank and is calibrated to apply 20 gallons per acre. How much Pesticide A should you add to the spray tank?

1. Determine the number of acres you can spray with each tank, using the following formula:

$$\text{Acres per tank} = \frac{\text{tank capacity (gallons per tank)}}{\text{Spray rate (gallons per acre)}} = \frac{200}{20} = 10 \text{ acres}$$

2. Determine the amount of pesticide to add to each tank, using the following formula:

Amount per tank = acres per tank x rate per acre.

With each tank, you cover 10 acres and you want to apply 2 quarts of product per acre:

Amount per tank = 10 x 2 = 20 quarts.

You need to add 20 quarts (5 gallons) of Pesticide A to each tank load.

Example: Broadcast application. Pesticide B is an 80 percent wettable powder formulation. After reading the label, you decide to apply 12 pounds per acre for perennial weed control. The area to treat is 150 feet wide and 180 feet long. Your backpack sprayer is equipped with a three-nozzle boom, has a 4-gallon tank, and is calibrated to apply 40 gallons per acre of spray solution. How much water and product do you add to the tank? (43,560 sq. ft. = 1 acre)

1. Calculate the area to be treated as follows:

150 x 180 feet = 27,000 square feet, which is equal to 0.62 acres (27,000 ÷ 43,560)

2. Calculate the amount of water needed to cover 0.62 acres, using this formula:

$$\frac{40 \text{ gallons}}{1 \text{ acre}} = \frac{Y \text{ gallons}}{0.62 \text{ acre}}$$

which is read as "40 gallons is to one acre as Y gallons is to 0.62 acre."

Cross-multiplying:

(Y x 1) = (40 x 0.62) = 24.8 gallons to treat 0.62 acre

3. With a 4-gallon tank, we will need more than six loads of solution; let's plan to mix seven loads.

$$\frac{24.8 \text{ gallons}}{7 \text{ loads}} = 3.54 \text{ gallons per load}$$

4. If we were spraying an acre, we would need 12 pounds of pesticide per 40 gallons of water (the per-acre output of our sprayer). However, we will be spraying only 3.54 gallons at a time. To determine the amount of pesticide to add per tank load, use the following formula:

$$\frac{12 \text{ pounds}}{40 \text{ gallons}} = \frac{Y \text{ pounds} =}{3.54 \text{ gallons}}$$

$$Y = \frac{12 \text{ x } 3.54}{40} = 1.06 \text{ pounds of Pesticide B in each tank load of 3.54 gallons}$$

Liquid Application on a Percentage Basis

Occasionally pesticide recommendations are expressed as amount of product per a specified volume of water. Such rates are expressed as "volume/volume" equivalents or as a percentage of product in the spray solution.

Example: Rate expressed as volume per volume. Pesticide C is recommended as a sanitary bin spray to control stored grain insects. Four gallons of product are recommended per 100 gallons of water. You want to prepare 75 gallons of solution. How much Pesticide C do you mix with the 75 gallons of water?

$$\frac{4 \text{ gallons Pesticide C}}{100 \text{ gallons water}} = \frac{Y \text{ gallons Pesticide C}}{75 \text{ gallons water}}$$

By cross multiplying:

100 x Y = 75 x 4

100 x Y = 300

Y = 3 gallons of Pesticide C per 75 gallons of water

GRANULAR APPLICATOR CALIBRATION

Occasionally, granular or pelleted pesticides are used for weed control. The need for accurate calibration is just as great for granular applicators as for sprayers.

The application rate of granular applicators depends on the size of the metered opening, the speed of the agitator

or rotor, travel speed, the roughness of the site, and the flowability of the granules. The flow rate of granules depends on particle size, density, type of granule, temperature, and humidity. The manufacturer's suggested setting should be used only as the initial setting for verification runs by the operator prior to use. A different applicator setting may be necessary for each pesticide applied; variations in flow rate also can occur with the same product from day to day or from site to site. It is therefore important to calibrate frequently to maintain the proper application rate.

Apart from the actual setting of the metering opening, ground speed is the most significant factor affecting the application rate. You must use the same ground speed during calibration that you intend to use during the application, and the speed must remain constant. However, gravity-flow applicators use a rotating agitator, with speed varying with ground speed. The flow of granules through the opening is not necessarily proportional to speed. A speed change of 1 mile per hour may cause a significant variation in the application rate.

Drop-through Spreaders

Drop-through spreaders usually are calibrated using catch pans. Chain or wire catch pans beneath the spreader to collect granules as they are discharged. After covering a distance equivalent to 1/50 acre (871 sq. ft.), weigh the granules collected in the catch pan to determine the application rate. Use the table below to select the appropriate travel distance for your spreader.

Swath width (feet)	Travel distance (feet)
1.5	581
2	436
3	290
4	218
5	174
6	145
7	124
8	109
9	97
10	87
11	79
12	73
15	58

If your spreader has a different width, use this formula to calculate the travel distance:

$$\text{travel distance in feet} = \frac{871}{\text{swath width in feet}}$$

For example, if you have a spreader that covers a 6.5-foot swath, the distance to travel is:

$$\frac{871}{6.5} = 134 \text{ feet}$$

The step-by-step procedure for calibrating a drop-through spreader is:

1. Before starting, calculate how much material should be applied in the calibration area. You need to know only the recommended rate per acre and multiply this value by 1/50 (remember you will cover 1/50 acre in the calibration exercise).
2. Measure out the travel distance as determined by the swath width of the spreader.
3. Securely attach a collection pan to the spreader.
4. Set the feeder gate control to the setting recommended in the owner's manual or on the product label.
5. Calibration must be done with the same granules you intend to use during application.
6. Operate the spreader in the premeasured calibration area at the speed you intend to use during application.
7. Weigh the amount of granules in ounces in the collection pan. Be sure to use a scale that can accurately measure to the nearest ounce.
8. Compare the amount of product collected in the calibration area with the amount calculated in Step 1 above. If they are within 5 percent of each other, the applicator is properly calibrated; if not, you need to adjust the feeder gate control and recalibrate.

Example: A broadcast application of Pesticide D is to be made at a rate of 60 pounds of product per acre. Your equipment broadcasts granules in a 15-foot swath width. After covering a distance of 58 feet, you collect 16 ounces of granules. Is your applicator properly calibrated?

1. Determine the amount of product in ounces that should be applied to the calibration area:

   (60 pounds) x (1/50) = 1.2 pounds x 16 ounces per pound = 19.2 ounces

2. Determine if the amount actually applied (16 ounces) is within 5 percent of the recommended rate (19.2 ounces):

   19.2 ounces x 0.05 (5%) = 0.96 ounces

If your applicator was properly calibrated, it should have applied between 18.2 and 20.2 ounces of product to the calibration area. It actually applied less. You therefore need to adjust the feeder gate control to apply more material and then recalibrate.

CHAPTER 4

Review Questions

Chapter 4: Calibration

Write the answers to the following questions and then check your answers with those in the back of the manual.

1. Why is calibration of various spray systems essential?

2. Calibration ensures that the correct amount of pesticide is delivered uniformly over the target area.
   A. True
   B. False

3. What happens to the flow rate if you increase the nozzle pressure or use a larger nozzle tip opening?
   A. Has no effect of the flow rate.
   B. Increases the flow rate.
   C. Decreases the flow rate.

4. To double the flow rate, you must increase the pressure:
   A. Twofold.
   B. Threefold.
   C. Fourfold.
   D. Fivefold.

5. If the throttle setting remains constant, and the speed doubles, the amount of spray per acre:
   A. Remains constant.
   B. Doubles
   C. Is reduced by half.
   D. Is reduced by one quarter.

6. Measuring and comparing the output of each nozzle to the average output of all the nozzles allows you to determine if:
   A. The pump is functioning properly.
   B. Any nozzle is worn or clogged.
   C. It is the right nozzle for the job.
   D. The pressure is accurate.

7. If the spray pattern is not uniform, you should:
   A. Check the boom height.
   B. Check the spacing and alignment of the nozzles on the boom.
   C. Check the operating pressure.
   D. Do all of the above.

8. You determine the distance to travel for calibration by:
   A. Using a formula with a constant and the nozzle spacing.
   B. Reading it from the pesticide label.
   C. Reading it from the tractor handbook.
   D. Setting an arbitrary distance based on the type of pesticide.

9. Why is there an operating pressure range for each type of nozzle?
   A. To prevent nozzle clogging.
   B. To relieve strain on the pump.
   C. To keep the spray pattern from distorting.
   D. To calculate the travel distance.

10. In a broadcast sprayer calibration, if the nozzle spacing is 30 inches, what is an appropriate distance to stake out in the field?
    A. 101 feet
    B. 136 feet
    C. 256 feet
    D. 1 acre

11. In Question 10, it took 20 seconds to travel the appropriate distance. What does this travel time tell you?
    A. How long you should measure the output from nozzles.
    B. How long it will take to spray the entire field.
    C. How long it will take to empty the tank.
    D. Whether the sprayer is properly calibrated.

12. When calibrating a broadcast sprayer, you find that the average nozzle output is 25 ounces for the recorded travel time. What is the spray rate in gallons per acre?

    A. 25 gallons per acre
    B. 30 gallons per acre
    C. 35 gallons per acre
    D. 40 gallons per acre

13. What can you do if your calibrated spray rate is less than the recommended rate stated on the label?

    A. Increase the pressure.
    B. Decrease travel speed.
    C. Increase nozzle tip size.
    D. B and / or C.

14. In a broadcast sprayer application, if the spray tank capacity is 150 gallons and the spray rate is 30 gallons per acre, how many acres can be sprayed per tank?

    A. 0.2 acres
    B. 0.5 acres
    C. 3 acres
    D. 5 acres

15. In Question 14, how much pesticide will you need to add per tank if the label recommends 4 quarts of product per acre?

    A. 10 quarts
    B. 20 quarts
    C. 30 quarts
    D. 40 quarts

16. How do you determine what rate of pesticide to apply?

    A. Use a formula.
    B. Read it off the spray tank.
    C. Read the pesticide label.
    D. All of the above.

17. The flow rate of dry granular pesticide products:

    A. Varies because of many factors such as particle size and humidity.
    B. Remains constant from product to product.
    C. Prevents accurate calibration.
    D. Allows for less frequent calibration than liquid products.

18. A broadcast application of granular pesticide is to be made at the rate of 30 pounds of product per acre. Your equipment broadcasts granules in a 10-foot swath. How many feet do you travel to calibrate your spreader?

    A. 218 feet
    B. 145 feet
    C. 87 feet
    D. 58 feet

CHAPTER 5

INSECT MANAGEMENT

LEARNING OBJECTIVES

After completely studying this chapter, you should:

- Understand how insects grow and develop.
- Understand the difference between simple and complete metamorphosis.
- Be able to identify general and major insect pests of alfalfa, corn, dry beans, soybeans, small grains, and sugar beets.
- Be able to describe the life cycles and habitats of the major field crop pests.

Insect damage reduces crop yield or quality, or contaminates the final product. Insects can also transmit plant diseases. To effectively control insect pests, you should understand how insects grow and develop.

GROWTH AND DEVELOPMENT

Growth

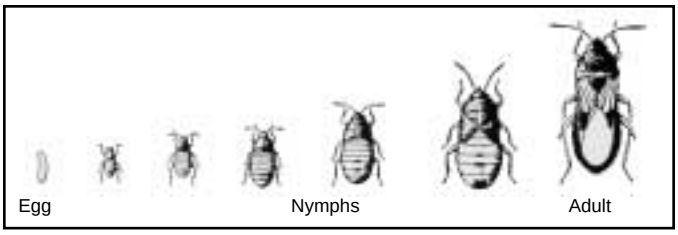
An insect's body is confined in a protective **exoskeleton**. This hard outer covering does not grow continuously. A new, soft exoskeleton is formed under the old one, and the old exoskeleton is shed—a process called molting. The new exoskeleton is larger and allows the insect to grow a little more. The new exoskeleton is soft and white at first, but it hardens and darkens in a few hours. After molting, which usually takes place in hiding, the insect resumes its normal activities.

Development

Insects are divided into groups according to the way they change during their development. The technical term for this change is ***metamorphosis***, which means "change in form." Pests of field crops undergo either simple or complete metamorphosis.

Group 1. Simple Metamorphosis

When insects that develop by simple metamorphosis hatch from their eggs, they resemble the adult insects except that the immatures, or ***nymphs***, do not have wings. Nymphs periodically molt, growing larger. After the final molt, nymphs become adults and generally have wings. Many pests of field crops such as potato leafhopper, sugarbeet root aphid, tarnished plant bug, and grasshoppers develop by simple metamorphosis. Nymphs and adults are often found together in the crop and usually eat the same food.



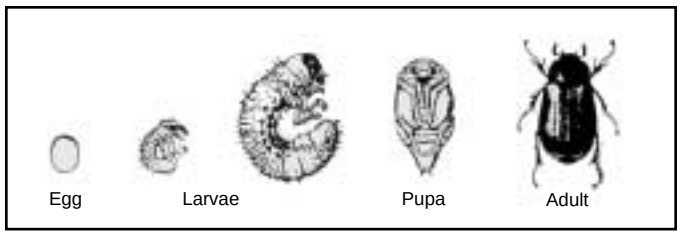
A plant bug is an example of an insect with simple metamorphosis.

Group 2. Complete Metamorphosis

Insects that develop by complete metamorphosis make a radical change in appearance from immature to adult. This major group includes beetles, moths, butterflies, flies, bees, and wasps.

In complete metamorphosis, newly hatched insects are called ***larvae***. Grubs, maggots, and caterpillars are types of larvae. The job of larvae is to eat and grow. Larvae molt four to six times and then change into ***pupae***. A pupa is an inactive stage of insect development. During pupation, the insect's body rearranges itself, resulting in a complete change in form from immature to adult insect. Insects undergoing complete metamorphosis have very different looking, larva and adult stages. Larvae and

adults are often so different that they do not eat the same food and need different habitats.



A beetle is an example of an insect with complete metamorphosis.

CONSIDERATIONS FOR PEST MANAGEMENT

The developmental stages of insects with complete metamorphosis support rather than compete with each other. It is as if they are two or three completely different animals with different needs and habitats, instead of a single species. The larvae feed and live in one habitat and sometimes leave that area to pupate a short distance away. The adult emerges and often eats a different food and lives in another area, returning to the larval feeding site only to lay eggs. An example is the European corn borer—the larva is a caterpillar living in corn; the adult is a moth. For this reason, species with complete metamorphosis are managed differently according to life stage, where each lives, and what each does. You will want to pay special attention to the following sections that discuss the life cycle and behavior of each insect pest.

INSECT PESTS OF ALFALFA

Alfalfa Weevil (*Hypera postica*)

Pest status: major pest.

Alfalfa weevil adult.

Characteristics and life cycle: This snout-nosed beetle was first found in Michigan in 1966. Adult weevils overwinter in alfalfa fields, fencerows, woodlots and other sheltered places. The adult is $^{3}/_{16}$ inch long with a broad, dark band down the middle of the back and chewing mouthparts at the end of a long, slender snout. Alfalfa weevils begin to feed on alfalfa in the spring as soon as growth starts. After two weeks of feeding, the female chews a hole and lays yellowish, brown eggs in the alfalfa stems. Eggs hatch in one to two weeks. The larvae are cream-colored to yellowish green with black heads and no legs and a distinct white stripe down the middle of the back. The larvae feed on leaf buds and terminal growing areas for three to four weeks. Full-grown larvae make cocoons on the leaves and pupate; adult weevils emerge between mid-June and mid-July. The new adults feed only a short time before preparing to overwinter and rarely cause much damage. There is one generation of alfalfa weevil per year.

Damage: Alfalfa weevil damage is a concern for the first cutting and the regrowth of the second cutting. Adults and larvae feed on leaves and stems. Small larvae feed on leaf buds and terminal growing areas. As larvae grow, they feed on the leaves, leaving only the veins. The majority of damage occurs between mid-May and mid-June. Severe infestations can affect regrowth and reduce yield, quality, and stand longevity.

Control: ***Cultural***—Cutting alfalfa at the bud stage will not only directly kill weevil larvae but also expose them to the environment and remove their food source.

Biological—In Michigan, at least three parasitic wasps attack adults and/or larvae. In most years, these biological control agents do an effective job of controlling alfalfa weevil, and pesticide applications are not necessary.

Chemical—Rarely required, a single insecticide application made at threshold will generally provide effective alfalfa weevil control. An insecticide application also kills the biological control agents, however, especially early in the season. Scouting methods and thresholds are available to make a management decision.

Potato Leafhopper (*Empoasca fabae*)

Pest status: key pest.

Potato leafhopper (nymph).

Potato leafhopper (adult).

Characteristics and life cycle: Potato leafhopper is the primary alfalfa pest each year. Adults migrate from the southern United States into Michigan in mid- to late May. The adult is a tiny, lime-green, translucent, wedge-shaped insect with sucking mouthparts. Eggs are laid in the stems and leaf petioles. A leafhopper nymph resembles an adult without fully developed wings. Potato leafhopper populations increase quickly, with a single generation taking only 21 days from egg to adult in a warm summer. There are multiple overlapping generations during the season.

Damage: Because potato leafhoppers migrate into the state, they usually attack only the second and third cuttings. Both adults and nymphs damage alfalfa by sucking plant fluids from the leaves. They inject a toxic substance as they feed that damages the plant cells and creates a characteristic V-shaped yellow marking on the leaf tip called "hopperburn." Heavy infestations cause leaves to yellow, curl, and die, may severely stunt plants, and reduce plant protein.

Control: ***Cultural***—Establishing a healthy alfalfa stand is the first defense against the potato leafhopper. A number of potato leafhopper-tolerant and hairy alfalfa varieties show reduced symptoms. If potato leafhopper populations reach the economic threshold close to cutting time, the alfalfa may be cut to reduce nymph populations. Adults, however, are very active, strong flyers, and may fly away only to return later.

Biological—Generalist predators such as lady beetles and lacewings feed on potato leafhoppers. However, these biological control agents usually do not provide sufficient control to prevent damage under moderate to heavy potato leafhopper pressure.

Chemical—Early detection is the key to keeping potato leafhopper populations under control. Beginning in mid-June, sample fields using a 15-inch-diameter sweep net to determine infestation levels. If samples exceed the economic threshold (Table 5.1), insecticide treatment is justified or, if practical, the field can be cut immediately. Remember, don't wait until visible damage occurs to treat for potato leafhopper, because heavily damaged plants may not recover.

Table 5.1: Potato leafhopper economic thresholds

Plant height (inches)	No. leafhoppers/ 100 sweeps
Under 3	20 adults
3 to 8	50 adults
8 to 12	100 adults and / or nymphs
12 to 14	200 adults and / or nymphs

Alfalfa fields are home to a large number of insects, and blooming alfalfa fields attract honeybees. Typically, only alfalfa weevil and potato leafhopper are of concern in reducing alfalfa yield and quality. All of the insecticides used to control alfalfa weevil and potato leafhopper are highly toxic to honeybees. If an insecticide application is required, avoid application to a field in bloom, and do not allow drift onto blooming weeds or nearby beehives. Also, neighboring beekeepers should be notified when and where applications will take place.

INSECT PESTS OF CORN

Armyworm (*Pseudaletia unipuncta*)

Pest status: occasional.

Characteristics and life cycle: Each year adult armyworms migrate into Michigan. The adult armyworm is a gray-brown moth with a 1-inch wingspan and a white dot on the center of the forewing. Female moths prefer to lay eggs on grasses or grains. Full-grown larvae are $1\frac{1}{2}$ to $1\frac{3}{4}$ inches long with two orange stripes along each side of the body and dark bands on the **abdominal prolegs** (the false, peglike legs on the abdomen of a caterpillar). There are two to three generations per year.

Armyworm damage in corn.

Damage: Armyworms feed on wild and cultivated grasses, especially corn and small grains. Severe defoliation results from larvae feeding on the leaves of seedlings and mature corn. Larvae may feed only on leaf margins or they may strip the plants, leaving only the stalks. Usually, the corn plant recovers from the damage as long as the growing tip has not been injured. Weedy corn or corn

that has been no-tilled into pasture, fallow ground, or a cover crop is at greater risk for damage. Armyworms can also migrate in large numbers from small grain fields to adjacent cornfields after the grain has matured. These large larval migrations can destroy a cornfield in one to two days.

Control: ***Cultural***—The elimination of grassy weeds from fields and field edges helps to reduce egg-laying sites and the potential for infestations and outbreaks.

Biological—In warm, dry weather, natural enemies usually keep armyworm populations under control.

Chemical—If armyworms deplete the grassy weed hosts and migrate , into a cornfield, an insecticide application may be necessary. Spot treatment of infested areas can provide sufficient control if the infestation is confined.

Fall armyworm (*Spodoptera frugiperda*)

Pest status: occasional.

Characteristics and life cycle: Native to the tropics, this late-season pest arrives from the Gulf Coast states. The adult moth is a mottled gray with a white spot near the tip of the forewing. Eggs are deposited in clusters on leaves and covered with hairs and wing scales from the female. The larvae vary in color but have three yellowish white lines from the head to tail and darker stripes on each side. Scattered along the body are black bumps (tubercles) with spines. A white inverted Y on the head capsule of the fall armyworm helps to distinguish it from other corn pests. Fall armyworm completes one to three generations per year and can not overwinter in areas where the ground freezes during the winter.

Damage: Fall armyworm causes more severe problems in late-planted corn. The larvae feed on developing leaves deep inside the whorl, occasionally killing the tassel before it emerges. Usually the plant will outgrow the damage if the tassel has not been injured. Larvae present late in the season feed on developing ears, causing damage similar to that of corn earworm.

Control: ***Cultural***—Avoiding late plantings helps to reduce the risk of fall armyworm damage. Ear damage by fall armyworm can be more abundant in long-season hybrids.

Biological—Parasitoids and predators provide some suppression of fall armyworms.

Chemical—Chemical control is usually not an economical option.

Corn Flea Beetle (*Chaetocnema pulicaria*)

Pest status: common but rarely causes economic damage to field corn.

Characteristics and life cycle: This native beetle is very small (1/16 inch long), shiny, and black with enlarged hind legs. It jumps like a flea when plants are disturbed. Flea beetles overwinter in Michigan at the base of grasses along field edges. In the spring, they emerge and feed

Corn flea beetle (M. Rice, Iowa State University).

on other grasses and winter wheat if no corn is available. Eggs are deposited in the soil and the larvae develop in the soil feeding on corn roots.

Damage: Adult corn flea beetles strip off the top layer of cells on a leaf, giving the leaf a scratched appearance. The most severe injury occurs during cold springs, when slow plant growth allows beetles more time to feed. The beetle also may transmit a bacterial disease, Stewart's wilt. Stewart's wilt can dramatically reduce yields on susceptible hybrids and lines of sweet corn, though it rarely causes a problem in field corn.

Control: ***Cultural***—Avoid early planting of susceptible hybrids or plant resistant sweet corn hybrids.

Chemical—Seed corn producers can be affected by Stewart's wilt and may need to use insecticides to control corn flea beetles.

Corn Rootworm

Pest status: occasional to common, depending on species.

Characteristics and life cycle: Three species of corn rootworm beetles occur in Michigan.

1. **Northern corn rootworm** (*Diabrotica barberi*)

The ¼-inch-long adult is pale to dark green with no markings on the wing coverings.

2. **Southern corn rootworm** (*Diabrotica undecimpunctata howardi*)

Also known as the spotted cucumber beetle, the adult is yellow-green with 12 black spots on the wing covers. The southern corn rootworm is more commonly a garden pest.

3. **Western corn rootworm** (*Diabrotica virgifera virgifera*)

This is the most common and serious pest species of rootworm in Michigan. Western corn rootworm adults are light yellow to light green with three black stripes on the wing covers that tend to blend together toward the back of the beetle.

Western corn rootworm (adult).

The northern and western corn rootworms overwinter as eggs in the soil and begin hatching in late May, with peak hatch in June. The white larva has a brown head and three pairs of small legs behind the head. After feeding on corn roots, the larvae pupate in the soil, and adult beetles begin to emerge in late June, with peak emergence in August. Each female can deposit as many as 1,000 eggs in the top few inches of soil, primarily in cornfields. Egg laying goes on until the first frost. During dry years, western corn rootworms eggs may be laid up to 1 foot deep. Corn rootworms have one generation per year.

Damage: ADULT—The adult beetles are usually active during silking and eat (clip) silks and pollen. If the adults emerge before pollen shed and begin feeding on the silks, poor kernel fill can occasionally result. Typically, the adults do not cause economic damage in field corn.

LARVAL—Corn rootworm larvae feed on root hairs, layer roots, and growing tips. In young plants, the damage can reduce plant stand and plant vigor. Root destruction also causes plant stress, decreases plant stability, and creates entry wounds for plant pathogens. Economic loss due to corn rootworm larval feeding depends on the number of larvae, the size of the root mass, soil moisture, nutrients, hybrid, and weather conditions. Root regeneration and establishment of brace roots can be inhibited if moisture and heat stress are present during peak root feeding. This may result in severe lodging. After the larvae pupate and the lodged plants try to regenerate roots, the plants may then straighten, resulting in a "gooseneck" appearance. The end result may be extreme yield reduction and harvest complications.

Control: ADULTS: Adult corn rootworms rarely cause economic damage, and it is not common practice to control them.

LARVAE: **Cultural**—In mid- to late summer, adult corn rootworms mate and lay eggs in the soil. These eggs overwinter, and the following spring, the larvae emerge and feed on corn roots. If no corn roots are available, the larvae will die in a few days. Crop rotation, therefore, is a very effective method of preventing economic loss from corn rootworm damage, and it eliminates treating first-year corn with soil insecticides.

Lodging caused by corn rootworm damage.

Chemical—Most growers who plant corn after corn apply a soil insecticide at planting. A product with a long residual, six to 10 weeks, is needed, because there is a four-to-six week time lapse between planting and corn rootworm egg hatch. Also, larvae feed for three to four weeks. Soil insecticide applications typically reduce larval survival by only 50 percent. Field scouting for adults the previous year will help to determine the corn rootworm pressure and whether a soil insecticide application will be needed the following year.

Western corn rootworm damage in first-year corn

A new behavior in the western corn rootworm, first noticed in Illinois, has also been found in Ohio and southwestern Michigan. The female western corn rootworm lays a portion of its eggs in other crops, such as soybeans. In strict corn-soybean rotations, the eggs hatch into corn the following spring and larvae feed on the roots. In parts of Illinois and Indiana, the rootworms cause extensive root injury, lodging, and yield reduction in rotated corn. To date, crop rotation is still an effective control option against corn rootworms in most parts of Michigan.

Western corn rootworm feeding on soybean (M. O'Neal, Michigan State University).

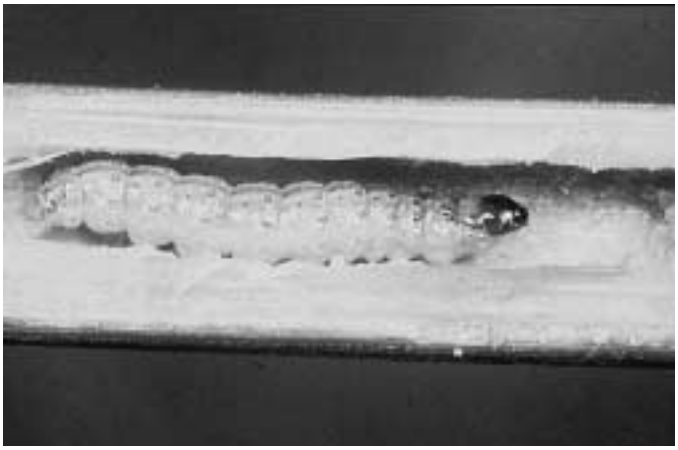
Field scouting and population sampling with yellow sticky cards placed just above the soybean canopy can indicate a potential problem for rotated corn. The mere presence of a few western corn rootworm beetles in soybeans does not mean that economic damage will occur if the field is rotated to corn. This is an emerging problem in Michigan; in 2000 it was confined to the southwestern part of the state. A soil insecticide may be needed in rotated corn if large numbers of beetles are trapped in the previous crop or if you are targeting other soil pests. Consult your county agriculture agent for updated information on scouting and treatment recommendations.

Yellow sticky card trapping corn rootworms in the soybean canopy (M. O'Neal, Michigan State University).

European Corn Borer (*Ostrinia nubilalis*)

Pest status: common.

Characteristics and life cycle: Introduced from Europe in the 1900s, the European corn borer has adapted to many hosts, including many agronomic and horticultural crops, and environmental conditions. European corn borers overwinter as full-grown larvae in corn debris and stubble on the soil surface. The larvae pupate in late April and May. Beginning in mid-June, adult moths emerge and mate in tall grasses. The female moth is 1 inch long with yellow-brown and medium brown, wavy lines on the wings, and a swollen abdomen when eggs are fully developed. The males have similar darker wing patterns and a hairy tuft at the tip of the abdomen. After mating, the female lays eggs on the undersides of corn leaves. Each egg mass contains 15 to 40 white eggs that overlap like fish scales. The egg mass darkens just before hatching, when the black heads of the larvae become visible ("black head" stage). The larvae hatch and feed on leaves, eventually moving to the whorl. Mature larvae are $^3/_4$ to 1 inch long with a medium to dark brown head and a creamy-white to gray body. As the larvae mature, they enter the stalk to feed, then pupate. Adult moths emerge in late July or early August to congregate and mate in grassy areas. The females then migrate to the cornfields and deposit their eggs on the leaves in the ear zone of the silking corn. This second generation of European corn borer feeds on the developing ears, causing kernel damage, or enters the stalk, ear shank or cob. Whether there are two or three generations per year depends on the temperature.



European corn borer in a cornstalk.

Damage: First generation European corn borer larvae feed primarily in the whorl and leaves, giving them a "shot-hole" appearance. Larger larvae feed within the leaf midrib and burrow into the stalk. Both of these activities disrupt normal movement of plant nutrients and water and have potential to reduce yield. Older fields with the tallest corn plants (i.e., early planted) are more likely to suffer first generation damage.

Second generation European corn borer larvae feed on the stalks, tassels, ear shanks, leaves, and kernels. Feeding on the ear shank causes the ear to drop, while stalk boring can lead to stalk breakage and harvesting difficulties and create entry wounds for stalk-rot fungi.

Younger fields with the shortest corn (i.e., late planted) are more likely to suffer second generation damage. Grain reduction also occurs from kernel feeding.

Control: ***Non-chemical***—Destruction of overwintering sites (cornstalks) in the fall kills many European corn borer larvae but does not reduce the population enough to provide adequate control the following year. Resistant hybrids and early-season hybrids are all useful in managing European corn borer.

Because older corn is more attractive to egg laying early in the season, there is often more first generation damage. Likewise, the second generation tends to attack late silking and pollen-shedding corn. Therefore, avoid extremely early and late plantings, or plant such fields with resistant hybrids. Concentrate scouting efforts on fields planted early and late.

A number of factors that are out of your control affect the potential economic loss caused by European corn borer damage. A series of cool evenings (below 65 degrees F) or a heavy rain can reduce the number of eggs laid or the survival of small larvae. In addition, young larvae can dehydrate and blow away on hot, windy days. Thus, conditions present during European corn borer mating, egg laying, and development of eggs and small larvae are critical in determining the population from year to year.

Lady beetle, *Harmonia axyridis* (H. Russell, Michigan State University).

Biological—Numerous natural enemies attack all life stages of European corn borer. Generalist predators such as ladybeetle larvae and adults, lacewing larvae, and minute pirate bugs feed on egg masses and small larvae. Other insects and birds eat large larvae and pupae. In locations with large populations of predators, their role in controlling European corn borer should be taken into consideration when determining a management strategy.

Though parasitoids were imported from Europe to control European corn borer, only a few became successfully established. The amount of control from these parasitoids varies from year to year and depends on the location and shape of each field.

Two main pathogens affect European corn borer populations. *Beauvaria bassiana* is a naturally occurring fungus that usually kills overwintering larvae, giving dead larvae a white, furry appearance. Most epidemics of *B. bassiana* occur during and after periods of rainfall late in the season when temperatures are around 85 degrees F. *Nosema pyrausta*, a protozoan, reduces European corn borer egg laying, kills some larvae, and increases overwintering mortality. An increase in stress caused by other factors increases the mortality caused by *N. pyrausta*.

Chemical—A decision to treat for European corn borer depends on many factors, including percent infestation, stage of plant, larval life stage, expected yield, and availability of equipment. European corn borer populations are largely influenced by the weather, so it is difficult to predict pest pressure from year to year. Scout for first generation European corn borers by examining plants for shot-holing. Second generation European corn borers are scouted by looking for egg masses laid on the undersides of leaves, especially in the ear zone.

Insecticide applications to whorl-stage corn can be effective against the first generation. Research and field experience shows that granular insecticides, though not commonly used in Michigan, control first generation European corn borer more efficiently than liquid insecticides. Timing is critical because once the larvae enter the stalk, insecticide applications are not effective. Thus, scouting is crucial for first generation European corn borer. Second generation European corn borer are more difficult to control and the timing of the application becomes even more critical.

A common soil bacterium, *Bacillus thuringiensis* subspecies *kurstaki* (Berliner), usually known as Bt, produces spores and protein crystals that are toxic to European corn borer larvae. Commercial formulations of Bt applied by conventional methods are effective against whorl, sheath, and collar feeding. Bt kills European corn borer only when it is ingested, and it is more effective on smaller larvae. Therefore, once the larvae burrow into the stalk, Bt is not effective. Though Bt kills European corn borer and other caterpillars, it is much less toxic to other organisms (including beneficial insects and humans) than broad-spectrum conventional insecticides.

Another option for controlling European corn borer is planting transgenic Bt corn. The gene for the Bt insecticide protein was put into the genetic structure of the plant, allowing the plant to produce Bt protein. When larvae feed on transgenic Bt corn plants, they ingest the proteins and die. Like Bt insecticide applications, transgenic Bt corn is much less toxic to beneficial insects such as lady beetles than conventional insecticides and offers safety for the grower.

INSECT PESTS OF DRY BEANS

Tarnished Plant Bug (*Lygus lineolaris*)

Pest status: common.

Characteristics and life cycle: The tarnished plant bug overwinters as an adult in leaf litter. The adult is 1/4 inch long, light brown with a tarnished appearance, and relatively long antennae and legs. There is usually a white triangle between

its "shoulders." Females deposit eggs into stems and midribs of plants. Nymphs are similar to the adult but smaller and without wings. Both nymphs and adults have sucking mouthparts.

Tarnished plant bug.

Damage: Tarnished plant bug adults and nymphs use their needlelike mouths to suck plant juices and inject toxic saliva. The saliva causes leaves to yellow and curl; severe damage may stunt plants. They can also feed on flowers and small pods so that beans shrivel.

Control: Scout fields from blossom to small pod development. A sweep net can be used to scout. The action threshold is one or more tarnished plant bugs per plant at the first flower to green pod stage.

Non-chemical—Tarnished plant bugs have a wide host range (dozens of crops and weeds), so there are no practical non-chemical control options at this time.

Chemical—Insecticide applications made to manage potato leafhoppers will also reduce tarnished plant bug populations. However, tarnished plant bugs are active and move about freely and thus avoid treatment. Therefore, feeding injury can resume soon after an insecticide application.

Potato Leafhopper (*Empoasca fabae*)

Pest status: common economic pest.

Characteristics and life cycle: Potato leafhopper adults migrate from the southern United States into Michigan in mid- to late May. The adult is a tiny, lime-green, translucent, wedge-shaped insect with sucking mouthparts. Eggs are laid in stems and leaf petioles. A nymphal leafhopper resembles an adult but lacks fully developed wings. Potato leafhopper populations increase quickly—a single generation takes only 21 days from egg to adult in a warm summer.

Damage: Adults and nymphs damage plants by sucking plant fluids from the leaves. They inject a toxic substance as they feed, creating a characteristic V-shaped, yellow marking on the leaf tip called "hopperburn." Heavy feeding causes leaves to yellow and curl, may severely stunt plants, and may kill plants.

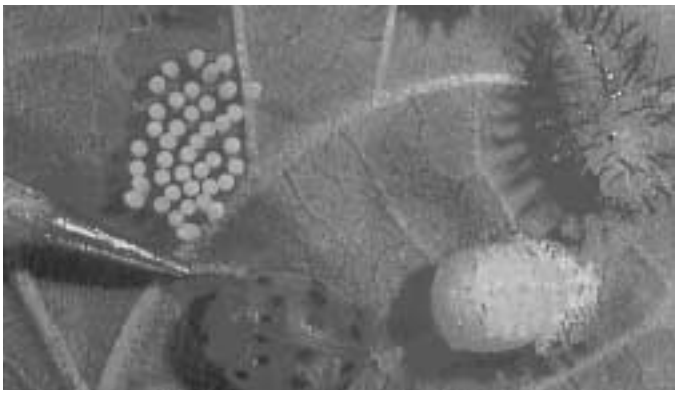
Control: ***Cultural***—Promoting healthy, vigorous plants minimizes the impact of potato leafhopper damage in fields.

Biological—Potato leafhoppers are native to the United States so there is no foreign biological control agent to import. Native predators and parasitoids play only a minor role in controlling populations. A fungal pathogen controls potato leafhopper under cool, moist conditions later in the summer.

Chemical—Early detection is the key to controlling potato leafhopper populations. Fields are sampled by examining leaves to determine the number of potato leafhoppers per leaf. Fields should be scouted regularly, especially after nearby alfalfa fields have been cut. If samples exceed five or more adults and / or nymphs per leaf, insecticide treatment is justified. Full coverage is necessary. Remember, adults are very active and strong flyers; after a field is treated, adult potato leafhoppers can recolonize from neighboring areas.

Mexican Bean Beetle (*Epilachna varivestris*)

Pest status: occasional.



Mexican bean beetle life cycle.

Characteristics and life cycle: Adult beetles overwinter in plant debris, along field edges, and in fencerows. Mexican bean beetles are oval and orange to copper-colored with 16 black spots in three distinct rows. In early spring, the adults move into bean fields. The females deposit clusters of up to 50 yellow-orange, oval eggs on the undersides of leaves. Larvae are up to $^{3}/_{8}$ inch long, oval, and yellowish with prominent spines on the back that gives them a fuzzy appearance. Generally, there are two generations per year.

Damage: Adults and larvae have chewing mouthparts and defoliate plants. They eat irregularly shaped holes from the lower leaf surface. This gives heavily infested plants a lacy, skeletonized appearance. If the infestation is large when leaves begin to yellow, larvae and adults may begin to feed on stems and pods. Yield reductions are

usually the result of defoliation, however, not pod feeding. Economic damage caused by Mexican bean beetle varies from year to year. Defoliation during flowering and pod development poses the greatest threat for economic loss.

Control: ***Non-chemical***—Avoid planting early—overwintering adults are attracted to early-emerging fields.

Biological—Many predators (such as stink bugs, nabids, and minute pirate bugs) and some parasitic wasps reduce Mexican bean beetle populations.

Chemical—Scout fields for larval and adult damage. Larvae are more damaging and harder to control than adults. Reducing adult populations early can eliminate the need for future applications.

INSECT PESTS OF SMALL GRAINS

Aphids

Pest status: common but usually not an economic problem.

Characteristics and life cycle: Aphids are small ($^1/_{16}$ to $^1/_8$ inch), pear-shaped, soft-bodied insects. They are found in a variety of colors. Aphids have projections called cornicles ("tailpipes") that extend from the rear of the body. They live in colonies made up of both winged and wingless insects. Female aphids do not have to mate with males to reproduce. They also produce live young (no eggs involved). This allows an aphid population to increase quickly.

Aphids on wheat.

Damage: Aphids use sucking mouthparts to remove plant juices from leaves and stems. If populations are large, their feeding causes plants to turn yellow and brown. They may feed on developing kernels. Aphids also vector a number of viruses, including barley yellow dwarf virus (see diseases of small grains).

Control: ***Cultural***—Quick stand establishment and vigorous plants help to reduce the impact of aphid damage.

Biological—Many common predators—including ladybeetle adults and larvae, lacewing larvae, and syrphid fly larvae—feed on aphids, keeping the population under control. There are also a number of parasitic wasps. After the adult wasp emerges from an infested aphid, it leaves behind a hard shell of its host, a "mummy". When scouting fields for aphids, it is important to note the number of aphid mummies to determine the effectiveness of the natural parasitoid population.

Chemical—Aphids are usually noticed when the grain heads, though they have been present on the grain since earlier in the season. Begin scouting fields at tillering, randomly examining plants for aphids. A threshold of 12 to 15 aphids per tiller during seedling to boot stage is usually used. Consult current MSU Extension bulletins for sampling methods. Most years, a careful and proper scouting program shows that chemical treatments are not needed.

Cereal Leaf Beetle (*Oulema melanopus*)

Pest status: occasional.

Characteristics and life cycle: The cereal leaf beetle was discovered in the United States in Berrien County, Michigan, in 1962. Adult beetles overwinter in plant stubble, under tree bark, in small crevices, and in similarly sheltered places. When temperatures reach the upper 60s F, the overwintering adults emerge to feed and mate. Soon after mating, the female lays single oblong eggs or chains of eggs on the upper surfaces of grain leaves. After hatching, the larvae cover all but their heads with their own fecal material, giving them a sluglike appearance and protecting them from predators. Larvae feed for about two weeks. Full-grown larvae shed the fecal covering, typically in early June, and move to the soil to pupate. A new generation of adults emerges and feeds for about three weeks before preparing to overwinter. The cereal leaf beetle has one generation per year in Michigan.

Damage: Larvae and adults have chewing mouthparts and feed on leaves between the veins. The adults chew entirely through the leaves; the larvae feed on the upper layer of the leaf. This gives a severely infested field a frosted appearance. Feeding before the boot stage reduces plant vigor; after boot, feeding on the flag leaf may reduce seed set and grain test weight. Damage is more serious when it occurs during early heading than during tillering.

Control: ***Cultural***—Hairy varieties are less desirable to cereal leaf beetle adults for egg laying and to larvae for feeding.

Biological—In the 1970s, a wasp egg parasitoid (*Anaphes flavipes*) was imported from Europe and distributed throughout Michigan. The spotted lady beetle (*Coleomegilla maculata lengi*) is an important predator that feeds on eggs early in the season. Larval parasitoids include three wasps, and a tachinid fly parasitoid attacks adults. In combination, the natural enemies of the cereal leaf beetle usually control this pest.

***Chemical*—**Cereal leaf beetle infestations often start along field borders of winter grains, with adults moving to preferred spring grains. Begin looking for adult feeding damage in the spring after the first warm spell (above 60 degrees F). Check adult-damaged fields for eggs and larvae. The decision to manage cereal leaf beetle is based on plant stage and the number and stage of development of the larvae. (See MSU Extension bulletin E-2549, *Insect Management in Wheat and Other Small Grains.*) Timing of application is extremely important, and applications are more effective when small rather than large larvae are present.

INSECT PESTS OF SOYBEANS

DEFOLIATORS

Many pests defoliate soybeans. Most are general feeders, capable of infesting many crops. High infestations of fall armyworms cause the most severe damage to soybeans. Fall armyworms prefer grass crops but can be a problem in weedy fields or when soybeans are double-cropped with small grains.

Taking whole-plant samples is best when you are scouting seedling-stage soybeans for defoliators. Sweep nets or ground cloths can be used for sampling larger plants. When making a management decision, it is important to consider all damage from all caterpillars (lepidopteran defoliators).

Bean Leaf Beetle (*Cerotoma trifurcata*)

Pest status: occasional.

Bean leaf beetle adult.

Characteristics and life cycle: Upon emergence in the spring, adult beetles feed on alfalfa. After the first alfalfa cutting and soybean emergence, bean leaf beetles move to soybean fields to lay eggs. Eggs are deposited in the soil and larvae feed on roots as they develop. Mature larvae build an earthen cell and pupate inside. Adult beetles emerge after approximately seven days. Usually peak emergence for this second generation is late August to mid-September. Second generation bean leaf beetles feed on soybeans and alfalfa before moving into overwintering sites.

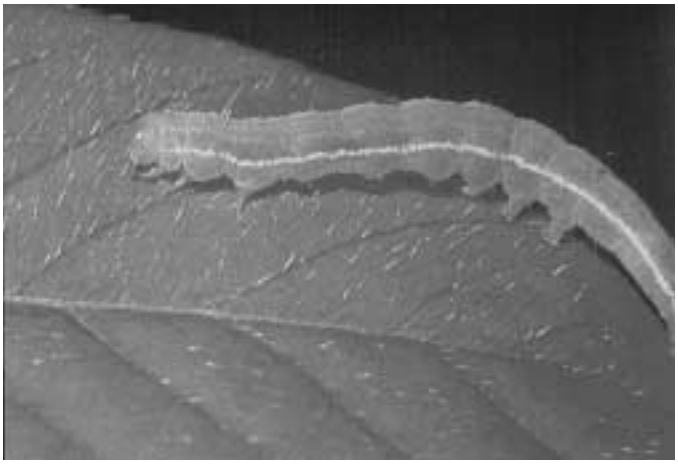
Damage: Bean leaf beetle larvae use their chewing mouthparts to eat roots, root hairs, and nodules. Adult beetles defoliate plants by chewing small, round holes in the leaves. Defoliation is a concern early in the season. Later in the season, beetles feed on pods all the way down to the seeds. This feeding damage creates lesions on the pod that remain visible at harvest and increase seed vulnerability to secondary pathogens. Seeds beneath lesions become shrunken, discolored, and sometimes moldy, resulting in loss of grain weight and quality.

Control: ***Cultural***—Planting soybeans as late as possible (within the recommended planting period for a variety) can reduce bean leaf beetle colonization.

***Chemical*—**Adult sampling should begin early in the season. Management is not usually necessary because of soybean tolerance of defoliation.

Green Cloverworm (*Plathypena scabra*)

Pest status: occasional outbreaks.



Green cloverworm.

Characteristics and life cycle: The adult moth migrates into Michigan each spring from overwintering grounds along the Gulf Coast. Eggs are laid on the undersides of leaves. The eggs turn brownish with red specks about 48 hours before hatching. Green cloverworm larvae (caterpillars) are pale green with two white stripes running horizontally along each side of the body. They have three pairs of abdominal prolegs plus one pair of **anal prolegs** (false, peglike legs near the anus of the caterpillar).

Damage: Green cloverworm larvae consume soybean foliage, giving leaves a tattered appearance.

Control: ***Biological***—A primary factor controlling green cloverworm populations is a disease caused by the fungus *Nomuraea rileyi*. Several predators and parasitoids also attack larvae.

Chemical—Insecticide applications are rarely used to manage green cloverworm.

Japanese Beetles (*Popillia japonica*)

Pest status: occasional.

Japanese beetle.

Characteristics and life cycle: Japanese beetles overwinter as larvae, commonly known as grubs, in the soil. Typically, they are found in grassy areas surrounding a field but can also be found in the soybean field. In late May or June, adults emerge and begin feeding on soybeans. Adult beetles are metallic green with reddish brown wing covers and white tufts on the abdomen. There is one generation per year.

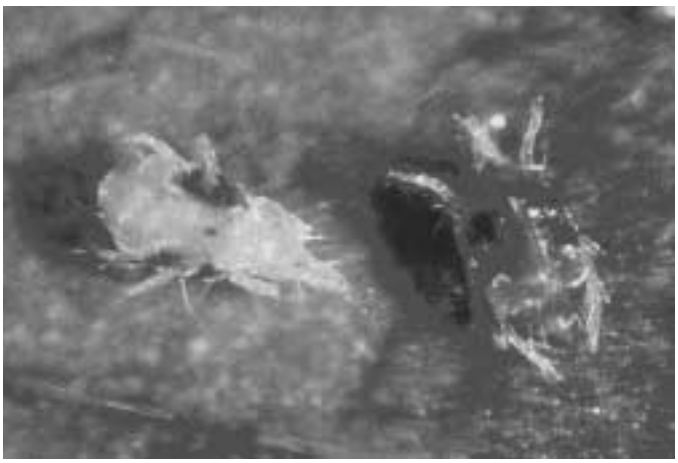
Damage: Adult beetles feed on leaf tissue between veins, giving the plant a skeletonized, lacy appearance. Responding to pheromones, Japanese beetles congregate. A soybean field may have multiple areas with large concentrations of beetles. Defoliation at these congregation sites can be heavy. Though Japanese beetle adults do most of the damage to soybeans, grubs do feed on soybean roots.

Control: Feeding by Japanese beetles alone usually is not sufficient to justify chemical treatment. Generally, a threshold of 25 percent defoliation due to combined feeding from Japanese beetles and other defoliators is used.

Two-spotted Spider Mite (*Tetranychus urticae*)

Pest status: occasional.

Characteristics and life cycle: This extremely small (0.3 to 0.4 mm) arthropod is more closely related to spiders than to insects and is distributed worldwide. Adults are greenish yellow to dull orange with eight legs and two large, black dots on their bodies. They produce noticeable webbing on heavily infested plants. Female mites lay eggs on the undersides of leaves. Spider mites go through a six-legged larval stage and two eight-legged nymphal stages. Rapid reproduction—four to 14 days per generation—results in exponential population growth.



Spider mite.

In northern states, spider mites overwinter as adults. Two-spotted spider mites disperse via air and by crawling, and they can infest a field extremely quickly. Spider mite populations increase quickly during hot, dry conditions, and damage is aggravated in water-stressed plants. Though a microscope is needed to correctly identify mites, the two-spotted spider mite is the only mite commonly found on soybeans in Michigan.

Damage: Feeding occurs on the undersides of leaves. The spider mite uses its needlelike mouthparts to pierce and suck the contents of individual plant cells. Infested leaves have small, white or yellow spots called stippling. This reduces the photosynthetic capacity of the leaf and creates leaf water stress. Eventually, with increased mite infestation, leaves become yellow, then brown, and drop from the plant. Maximum infestation of 1,000 spider mites per leaf causes complete defoliation. Early-season attacks can reduce overall plant growth.

Control: ***Biological***—The fungal pathogen *Neozygites floridana* is the most effective natural enemy of the two-spotted spider mite. Specific to spider mites, this pathogen attacks all mite stages by attaching to the mite's legs or body. Infected mites usually have a waxy or cloudy appearance and die within one to three days after infection. The effectiveness of this fungal pathogen depends on environmental conditions—it requires a temperature below 89 degrees F (29 degrees C) and at least 90 percent relative humidity for 12 to 24 hours.

Chemical—Begin sampling along field edges, closely examining leaves in the middle and lower canopy for stippling. Herbicide injury may resemble mite damage, so use a hand lens to confirm the presence of mites. Unfortunately, by the time that damage has been recognized, mites have infested the entire field. Late-season treatments may be difficult because of the 21- to 28-day preharvest intervals for most labeled chemicals. Mite populations can recover rapidly after treatment, adding to the expense and difficulty of control. They also have a tremendous capacity to develop insecticide resistance.

Soybean Aphid (*Aphis glycines*)

Soybean aphids.

In 2000, a new pest of soybeans, the soybean aphid (*Aphis glycines*), was detected in Michigan. Soybean aphids are small ($^1/_{16}$ to $^1/_8$ inch), pear-shaped, soft-bodied insects that live in colonies made up of both winged and wingless insects. Female aphids do not have to mate with males to reproduce. This allows an aphid population to increase quickly. Though aphids have been found across the state, the heaviest infestations to date (2000) have been in southwestern Michigan.

Soybean aphids have sucking mouthparts and remove water and nutrients from leaves and stems. The impact of soybean aphids on Michigan soybean production is not known. Research is underway to determine thresholds and treatment guidelines. Consult your county agriculture agent for updated information on scouting and treatment recommendations.

INSECT PESTS OF SUGAR BEETS

Sugar Beet Root Aphid (*Pemphigus betae*)

Pest status: localized occasional pest.

Sugar beet root aphid on sugar beets.

Characteristics and life cycle: Sugar beet root aphids are localized pests. Adult females overwinter in soil. In spring, they move to roots of lambsquarter and then to beets later in the season, producing young. Aphids present during the field season are all female and reproduce without mating. There are multiple generations per year.

Damage: Adults and nymphs use their sucking mouthparts to remove plant fluids from beet roots. This reduces root yield, sugar content, and juice purity. Sugar beet root aphids secrete a white, waxy material, which remains on colonized roots and interferes with water uptake. In severe infestations, beet leaves turn yellowish green and plants shrink and wilt.

Control: ***Non-chemical***—In fields where aphids have overwintered in the soil, crop rotation (three or more years) and good weed control reduce infestations. Resistant varieties are available.

Chemical—Consult current MSU Extension bulletins for current insecticide recommendations.

Spinach Leaf Miner (*Pegomya hyoscyami*)

Pest status: occasional.

Characteristics and life cycle: In late April and May, the adult spinach leaf miner emerges from its overwintering site in the soil. The adult fly resembles a housefly. Adult females deposit small, whitish eggs on the undersides of sugar beet leaves. Larvae (maggots) feed inside leaves and pupate in the soil. There are several generations per year.

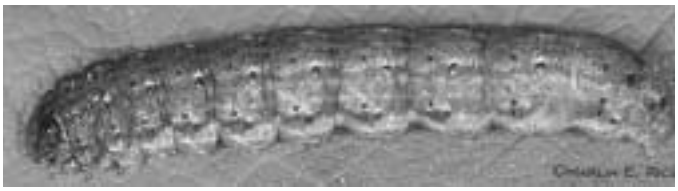
Damage: The spinach leaf miner is an occasional pest that rarely causes economic losses. The larvae feed between the upper and lower surfaces of the leaf tissue, forming a characteristic tunnel or "mine." As the maggots grow, the mines enlarge, forming blotches.

Spinach leafminer damage on sugarbeets.

Control: ***Chemical***—Insecticides should be applied when eggs are present on 50 percent or more of small plants and when the first mines are seen.

GENERAL INSECT PESTS

Cutworms



Black cutworm (M. Rice, Iowa State University).

Characteristics and life cycle: Various cutworms occasionally attack Michigan crops. Some overwinter in Michigan; others migrate to Michigan as adults each spring. Adult cutworms are moths. The larvae (caterpillars) are up to 2 inches long and come in a variety of colors (black, tan, greenish yellow) with a row of light yellow spots down the back. Each cutworm species has a slightly different life cycle and feeding behavior.

Damage: With their chewing mouthparts, larvae feed on leaves and cut stems. New seedlings are at the greatest risk for damage.

Control: Because several species of cutworms attack field crops in Michigan, correct identification is extremely important to adequately control the pest. Infestations are sporadic, so scouting fields and early diagnosis are also necessary. Also, because infestations are sporadic, foliar insecticides (curative) are recommended rather than soil insecticides at planting (preventive).

Grubs

Grub.

Characteristics and life cycle: Grubs are the C-shaped larval stage of beetles. Many are turf pests, but others occasionally cause damage in field crops. True white grubs are the larvae of May and June beetles; they require three years to complete development. Other grubs are the larvae of Japanese beetles or chafers; they require only a year to complete their life cycle (annual grubs). Correct identification of a grub problem is key to recommending control options.

Damage: Grubs prefer to feed on the roots of grasses, but they can cause irregular emergence, reduced plant stand, stunting, and wilting by feeding on the roots and root hairs of field crops. They can also sever taproots.

Control: ***Non-chemical***—Spring and summer plowing of established sod is recommended before a crop is planted. Predators such as birds play a minor role in grub management.

Chemical—Depending on the crop, a soil insecticide can be applied in-furrow or banded at time of planting. Chemical treatment is not usually required, however.

Wireworms (*Limonius* spp.)

Wireworms.

Characteristics and life cycle: Wireworms are the larval stage of click beetles. They are slender and shiny brown with wiry, segmented bodies. Larvae live for two to six years in the soil. Because of the long life cycle, crops planted into less disturbed ground (sod, pasture, old alfalfa, or reduced tillage fields) are at a greater risk for wireworm damage.

Damage: Wireworms feed on seeds and roots. They can reduce plant stand by preventing seed germination and attacking young plants.

Control: ***Non-chemical***—Spring and summer plowing of established sod is recommended before a crop is planted.

Chemical—A seed treatment or insecticide application at planting can help protect the crop from wireworm damage.

Seedcorn Maggot (*Hylemya platura*)

Characteristics and life cycle: Seedcorn maggots are small ($1/4$ inch), white maggots. The adults are small, gray flies that emerge in early spring to lay eggs in disturbed soil with high organic matter (for example, a field with manure or plowed cover crops). The maggots feed for one to three weeks and then pupate in the soil. There are multiple generations per year.

Damage: Seedcorn maggots are usually a problem during cold, wet springs and in soils with high organic mate-

rial. Feeding on germinating seeds, they may cause variable emergence, stand loss, or delayed development. They also create an entrance for disease organisms.

Control: ***Non-chemical***—Using reduced tillage, planting later in the season, and shallow planting in a well prepared seed bed decrease seedcorn maggot damage potential.

Chemical—If a maggot problem is expected, treating seed with an insecticide before planting is the most effective and convenient control method. Though more expensive, a soil insecticide can be applied if seed and planter box treatments are not possible.

CHAPTER 5

Review Questions

Chapter 5: Insect management

Write the answers to the following questions and then check your answers with those in the back of the manual.

1. Insect damage can result in:
   A. An unmarketable product.
   B. Disease transmission.
   C. Yield reduction.
   D. All of the above.

2. Molting is the process of shedding an old skeleton to reveal a new, larger exoskeleton.
   A. True.
   B. False.

3. Define metamorphosis.

4-8. Match the following forms of metamorphosis with the correct statement.

A. Simple

B. Complete

C. Both simple and complete

4. ___ Immature insects resemble adults.
5. ___ Adult and nymphs usually live in the same environment.
6. ___ Adult insects have wings.
7. ___ Immature insects do not look like the adults.
8. ___ Immature insects are referred to as larvae.

9. During which insect life stage does an insect undergo a complete change?
   A. Nymph
   B. Larva
   C. Pupa
   D. Adult

10. The corn rootworm goes through which type of metamorphosis?
    A. Simple
    B. Complete

11. Why is it important to understand an insect's life cycle for pest management?

12-18. Match the following insects with the correct statement below. Answers can be used more than once.

A. Alfalfa weevil
B. Potato leafhopper
C. Corn flea beetle
D. Armyworm
E. European corn borer

12. ___ Damage causes "hopperburn."
13. ___ Occasional pest of corn that can migrate in large numbers.
14. ___ Transgenic Bt corn plants are used to control.
15. ___ Primarily feeds on alfalfa leaves and stems in the spring.
16. ___Transmits Stewart's wilt.
17. ___Begin sampling alfalfa using a sweep net in mid-June.
18. ___ Feeds on leaves and burrows into corn stalks.

19. The larval corn rootworm causes damage to corn by feeding on the:

A. Silks.
B. Root hairs and root tips.
C. Ear shank.
D. Foliage.

20. Corn-soybean crop rotations do not control the variant _____ corn rootworm populations.

A. Northern
B. Southern
C. Western
D. Eastern

21. First generation European corn borers feed primarily in the:

A. Ear.
B. Shank.
C. Whorl.
D. Roots.

22. European corn borer feeding can result in:

A. Ear drop.
B. Stalk breakage.
C. Grain reduction.
D. All of the above.

23. The tarnished plant bug has what type of mouth parts?

A. Chewing.
B. Sucking.
C. Rasping.

24. Aphids and leafhoppers can spread plant disease.

A. True
B. False

25. Which insect has chewing mouthparts and usually moves to soybeans after the first cutting of alfalfa?

A. Spider mites.
B. Green cloverworms.
C. Bean leaf beetles.
D. Aphids.

26. Which of the following larvae is a common predator of aphids?

A. Lacewing
B Monarch
C. Housefly
D. None of the above

27. Fungal pathogens usually keep which two soybean pests from reaching high pest densities?

A. Bean leaf beetle and green cloverworm.
B. Two-spotted spider mite and bean leaf beetle.
C. Two-spotted spider mite and green cloverworm.
D. Bean leaf beetle and lepidopteran defoliators.

28-31. Match the following insects with the characteristics given below.

A. Cutworms
B. Grubs
C. Wireworms
D. Seedcorn maggot

28. ___ Prefer to feed on grass roots.
29. ___ Can live for two to six years in the soil.
30. ___ Feeds on leaves and stems.
31. ___ More commonly a problem during a cold, wet spring.

32. A farmer complains that a large group of caterpillars has just moved into his / her corn field and eaten all the leaves off the plants. This pest is most likely:

    A. Corn earworm.
    B. Armyworm.
    C. Green cloverworm.
    D. Wireworm.

33. It is difficult to control this insect in alfalfa and dry beans because adults are very mobile and often quickly reinfest fields after a pesticide application.

    A. Potato leafhopper
    B. Aphids
    C. Mites
    D. None of the above

34. Aphids must mate to produce offspring.

    A. True
    B. False

35. Which of the following insects does NOT have sucking mouthparts?

    A. Alfalfa weevil
    B. Potato leafhopper
    C. Sugar beet root aphid
    D. Tarnished plant bug

CHAPTER 6

WEED MANAGEMENT

LEARNING OBJECTIVES

After completely studying this chapter, you should:

- Be able to define a weed and its four stages of development.
- Understand the differences between annual, biennial, and perennial weeds.
- Be able to give examples of cultural weed controls.
- Know the advantages and disadvantages of the various methods of herbicide applications.
- Understand herbicide carryover and how to prevent it.
- Know what herbicide adjuvants are.
- Understand the weed control problems in conservation tillage systems.

Weeds are plants growing where they are not wanted. They can reduce field crop yields by competing for water, nutrients, and light. Some weeds release toxins that inhibit crop growth, and others may harbor insects, diseases, or nematodes that attack crops. Weeds often interfere with harvesting operations, and at times contamination with weed seeds or other plant parts may render a crop unfit for market. Profitable crop production depends on effective weed control.

DEVELOPMENT STAGES

All crop plants and weeds have four stages of development:

- SEEDLING—small, delicate, newly emerged plants.
- VEGETATIVE—plant grows quickly producing stems, roots, and leaves.
- SEED PRODUCTION—plant's energy is directed into producing flowers and seeds.
- MATURITY—plant produces little or no energy. Some plants begin to dry out or desiccate.

LIFE CYCLES OF WEEDS

Weeds can also be classified according to how long it takes them to complete their development or life cycle. The three types of plant life cycles for weeds are annual, biennial, and perennial.

ANNUAL

Plants that complete their life cycle in one year are **annuals**. They germinate from seed, grow, mature, produce seed, and die in one year or less. Annuals reproduce by seed only and do not have any vegetative reproductive parts. Summer annuals germinate from seed in the spring, flower and produce seed during the summer, and die in the summer or fall. These are the most common annual weeds found in field crops. Winter annuals germinate from seed in the fall and die in late spring or early summer the following year. Annual weeds are easiest to control at the seedling stage.

Cocklebur.

BIENNIAL

Biennials are plants that complete their growth in two years. The first year, the plant produces leaves and stores food. The second year, it produces fruits and seeds. Biennial weeds are most commonly found in no-till fields, pastures, and fencerows that are not mowed. They are easiest to control in the seedling stage.

Bull thistle is a biennial.

PERENNIAL

Perennials are plants that live for two or more years. Perennials can reproduce by seed or vegetatively. The plant parts that allow perennials to spread without producing seeds include **stolons** (creeping aboveground stems—e.g., white clover and strawberries), **rhizomes** (creeping belowground stems —e.g., milkweed, quackgrass), **tubers** (enlarged underground stems—e.g., potato, yellow nutsedge), and **bulbs** (underground stem covered by fleshy leaves—e.g., tulip). Because perennial weeds can propagate (spread) underground, they can be the most difficult weeds to control. Removing the aboveground vegetation will not stop the weed from spreading.

Johnsongrass is a creeping perennial.

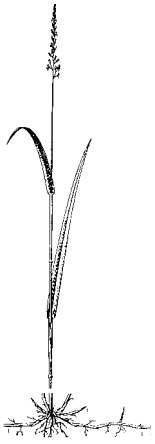
Annuals, biennials, and perennials can reproduce from seed. Many weeds produce large quantities of seeds. Seeds are easily dispersed across a field by wind, rain, machinery, animals, and people. Weed seeds can germinate after being dormant for long periods of time. They can also tolerate extremes in weather such as temperature and moisture. To prevent seed dispersal, you should control weeds before they produce seeds.

COMMON WEEDS IN MICHIGAN

GRASS AND GRASSLIKE WEEDS

Annuals

- Barnyardgrass
- Large crabgrass
- Smooth crabgrass
- Giant foxtail
- Yellow foxtail
- Green foxtail
- Fall panicum
- Wild-proso millet
- Witchgrass



Grassplant.

Perennials

- Johnsongrass
- Yellow nutsedge
- Quackgrass

Yellow Nutsedge.

BROADLEAF WEEDS

Annuals

- Ladysthumb
- Pennsylvania smartweed
- Wild buckwheat
- Common lambsquarters
- Redroot pigweed
- Eastern black nightshade
- Common cocklebur
- Jimsonweed
- Common purslane
- Common ragweed
- Giant ragweed
- Velvetleaf
- Common chickweed
- Shepherd's-purse
- Horseweed (Marestail)
- Prickly lettuce
- Wild mustard
- Yellow rocket

Redroot Pigweed.

Velvetleaf.

Biennials

- White campion
- Wild carrot
- Bull thistle

Perennials

- Milkweed
- Hemp dogbane
- Canadian thistle
- Dandelion
- Field bindweed
- Perennial sow thistle

WEED CONTROL

CULTURAL CONTROL

Crop competition is a very useful method of weed control. Maintaining production practices that optimize crop growth means the crop plants can compete more effectively with weeds. Several crop management practices can improve the competitive ability of the crop: crop and variety selection, planting date, population, soil fertility, drainage, etc. Recommended crop production practices are also beneficial weed control practices.

Crop rotation may also be helpful in maintaining adequate weed control. Many weeds cannot tolerate crop rotation.

MECHANICAL CONTROL

Tillage buries weeds or destroys their underground plant parts. Small annual and biennial seedlings are more effectively controlled with tillage. However, disturbing the soil can bring new weed seeds near the soil surface and create another weed problem.

CHEMICAL CONTROL

The first step in successful chemical weed control is the correct identification of the weeds. Annual weeds are easier to kill when they are small seedlings and when conditions favor rapid growth. However, crop plants are also easily injured under these conditions. Selective herbicides should control the weeds with little or no injury to the crop.

Timing and rate of herbicide application are very important in chemical weed control. Applying herbicides at the wrong time often results in poor weed control and crop injury.

TYPES OF HERBICIDES

Chemical weed control can be obtained with herbicides applied either preplant incorporated, preemergence, or postemergence. Many herbicides can be applied by more than one of these methods.

Preplant Herbicide Soil Applications and Incorporation

Preplant herbicide soil applications and incorporation are herbicide applications that are applied and incorporated into the soil before planting. Incorporation of some herbicides is required to prevent them from volatilizing (becoming a gas) or decomposing in the sun.

Advantages of preplant soil applications and incorporation:

- Early weed control reduces weed competition with the crop.
- Wet weather will not delay cultivation or herbicide application to control weeds.
- Preplant soil application and incorporation is less dependent on rainfall for herbicide activation than preemergence herbicide applications.

Disadvantages of preplant soil applications and incorporation:

- Incorporating the herbicide too deep in the soil can reduce weed control.
- A “streaking” pattern of good and poor weed c ontrol can result from incomplete soil incorporation.
- Growers apply herbicide without identifiying the weeds. They are preventive applications.
- It is incompatible with a no-till system.

Preemergence Herbicide Applications

Preemergence herbicide applications are applied to the soil surface after the crop has been planted but before the crop or weed seedlings emerge. Typically, preemergence herbicide applications require rainfall within one week following the application to ensure that the herbicide moves through the soil.

Advantages of preemergence applications:

- Reduce weed competition for crop with early control of weeds.

- Can be used in all tillage systems.
- Planting and herbicide application may be done at the same time.

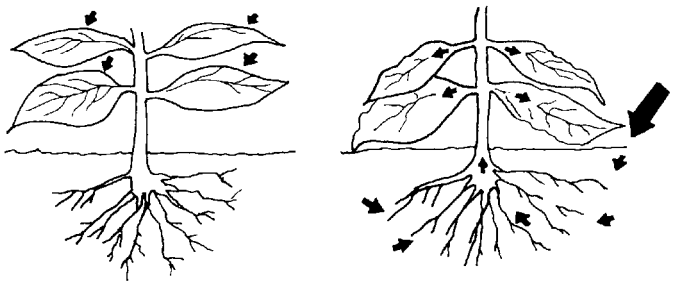
Disadvantages of preemergence applications:

- Depend on rainfall; ineffective in dry soil conditions.
- On sandy soil, heavy rains may move the herbicide down in the soil to the germinating crop seed and cause injury.
- Growers apply herbicide without identifying the weeds. They are preventive applications.

Postemergence Herbicide Applications

Postemergence herbicide applications are applied to the foliage of the weed after crop and weed have emerged. There are two types of postemergence herbicides: contact and systemic. **Contact herbicides** kill only the plant parts that they touch. Typically, the aboveground parts of a weed, such as the leaves and stems, turn brown and die. Contact herbicides are commonly used to control annuals.

Systemic or translocated herbicides are absorbed by the weed's roots or leaves and moved throughout the plant. Translocated herbicides are more effective against perennial weeds because the herbicide reaches all parts of the plant. However, translocated herbicides may take up to three weeks to kill the weeds.



Contact Herbicide

Translocated Herbicide

Advantages of postemergent applications:

- Herbicide is applied after the weed problem occurs (remedial application).
- Less susceptible to environmental conditions after the herbicide application.
- Useful for spot treatments.
- Postemergent herbicide applications have short or no soil residual.

Disadvantages of postemergent applications:

- Postemergent herbicides are environmentally sensitive at this time of application.
- Weeds must be correctly identified.
- Timing of the application is critical for effective weed control.
- Postemergent herbicides should not be applied to wet foliage.
- Weather may not permit a herbicide application at the proper time.

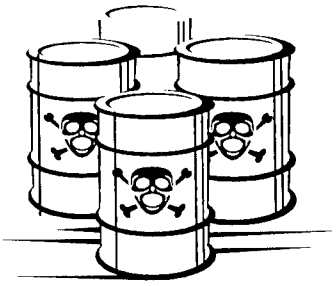
HERBICIDE CARRYOVER

A potential problem of herbicide applications is **herbicide carryover**. This occurs when a herbicide does not break down during the season of application and persists in sufficient quantities to injure succeeding crops. The breakdown of herbicides is a chemical and/or microbial process. Generally the rate of breakdown increases with soil temperature. Very dry conditions during the summer and early fall often increase the potential for carryover of many herbicides.

Herbicide carryover is also influenced by the rate of application, herbicide distribution across a field, soil type, and time. When herbicides are used above the labeled rate and/or not uniformly distributed, herbicide carryover problems may result. Poor distribution is generally the result of improper calibration or agitation, sprayer overlapping, or non-uniform soil incorporation.

Vegetable and ornamental crops are often more sensitive to herbicide carryover than field crops. To reduce the potential of herbicide carryover, read and follow all pesticide label directions. Herbicide labels contain restrictions on the interval between application and planting of various crops. Consult the current MSU Extension bulletin E-434, *Weed Control Guide for Field Crops*, for more information on herbicides.

HERBICIDE COMBINATIONS



Herbicides are commonly combined and applied as a tank mix. Combinations are used to give more consistent control or a broader spectrum weed control, to decrease herbicide carryover, or to obtain adequate season-long weed control. Proper application methods must be followed for each herbicide detailed on the EPA-approved pesticide label. Remember always to read the pesticide label before combining or applying herbicides.

HERBICIDE ADDITIVES (ADJUVANTS)

An **adjuvant** is any substance added to a herbicide to enhance its effectiveness. Many commercially available herbicide formulations contain their own particular set of adjuvants to optimize the performance, mixing, and handling of the active ingredient. Sometimes additional additives are required for specific applications or herbicide combinations. The pesticide label will explain how and when to use the necessary adjuvants.

Additives are used primarily with postemergence herbicide applications to improve the coverage of leaf surfaces and increase herbicide penetration into the leaf. Additives do not increase the effectiveness of soil-applied herbicides.

HERBICIDE COMPATIBILITY PROBLEMS

Compatibility problems in tank mixing herbicides usually occur when applicants do not follow mixing directions. Some common causes of compatibility problems are mixing two herbicides in the wrong order (for example, adding an emulsifiable concentrate to the spray tank before suspending a wettable powder), insufficient agitation, excessive agitation, and air leaks. Problems can also occur when the carrier is a fertilizer such as 28 percent nitrogen or other non-water substances. You should test for herbicide compatibility in a small container before mixing a large tank. If compatibility problems occur, the addition of compatibility agents may help.

CHAPTER 6

Review Questions

Chapter 6: Weed Management

Write the answers to the following questions and then check your answers with those in the back of the manual.

1. Define a weed.

2. Plants that complete their life cycle in one year are:
   A. Biennials.
   B. Annuals.
   C. Perennials.
   D. None of the above.

3. An aboveground creeping stem is called a:
   A. Rhizome.
   B. Stolon.
   C. Tuber.
   D. Bulb.

4. Weeds are easiest to control at the:
   A. Reproductive stage.
   B. Vegetative stage.
   C. Seedling stage.
   D. Mature stage.

5. Which of the following is an example of a broadleaf weed?
   A. Quackgrass.
   B. Green foxtail.
   C. Wild-proso millet.
   D. Common ragweed.

6. An example of a perennial grass weed is:
   A. Quackgrass.
   B. Wild carrot.
   C. Barnyard grass.
   D. Smooth crabgrass.

7. Reducing the competition between a crop and weeds by changing the planting population of the crop is an example of:
   A. Biological weed control.
   B. Cultural weed control.
   C. Chemical weed control.
   D. Mechanical weed control.

8. Preemergence herbicides generally require rainfall within a week of application to incorporate the herbicide in the soil.
   A. True
   B. False

9. Which of the following is true of preplant incorporated herbicide applications?

   A. They provide early weed control.

   B. They can be used in all tillage systems.

   C. They typically cause more crop injury than postemergence herbicide applications.

   D. They are not affected by soil composition and moisture.

10. List two advantages and two disadvantages to postemergence herbicide applications.

11. Systemic herbicides kill weeds on contact.

   A. True.

   B. False.

12. A preventive herbicide application occurs _____ weeds have emerged.

   A. before

   B. after

13. A grower has a quackgrass problem in a soybean field where the soybeans already have three (3) leaves. Which type of herbicide application would you use to control the quackgrass?

   A. Preplant soil incorporated

   B. Postemergent

   C. Preemergent

   D. None of the above

14. The best way to reduce the potential of herbicide carryover is to follow the pesticide label directions.

   A. True

   B. False

15. What is a herbicide adjuvant?

16. It is **not** necessary to test for herbicide compatibility before mixing a large tank.

   A. True

   B. False

CHAPTER 7

DISEASE MANAGEMENT

LEARNING OBJECTIVES

After completely studying this chapter, you should:

- Be able to define non-infectious and infectious disease.
- Understand how fungi, bacteria, and viruses produce disease.
- Understand the disease triangle and the disease cycle.
- Understand control methods specific to disease management.
- List the major diseases affecting alfalfa, corn, dry beans, soybeans, small grains, and sugarbeets.

INTRODUCTION

Diseases are the most difficult plant injury to diagnose and manage. A plant **disease** is any condition that does not allow the plant to function normally. **Non-infectious plant diseases** are caused by non-living agents or cultural and environmental damage such as drought, soil compaction, hail, wind, toxic chemicals, nutrient deficiency, and temperature or moisture extremes. Non-infectious disease can not reproduce and spread from plant to plant.

Disease symptoms such as wilting, stunting, and yellowing of leaves may appear suddenly on a plant with a non-infectious disease. Few non-infectious diseases can be corrected or avoided, and often the disease symptoms resemble those of infectious diseases. For example, nutrient deficiency symptoms often resemble symptoms of root rot. The remainder of this manual focuses on infectious plant diseases and their management.

An **infectious plant disease** is caused by a living organism that attacks and feeds on the host plant. The disease-causing organism is called a **pathogen**. In Michigan, fungi, bacteria, and viruses are pathogens for field crops. Pathogens are spread from diseased plants to healthy plants by wind, rain, soil, people, machinery, and insects.

FUNGI

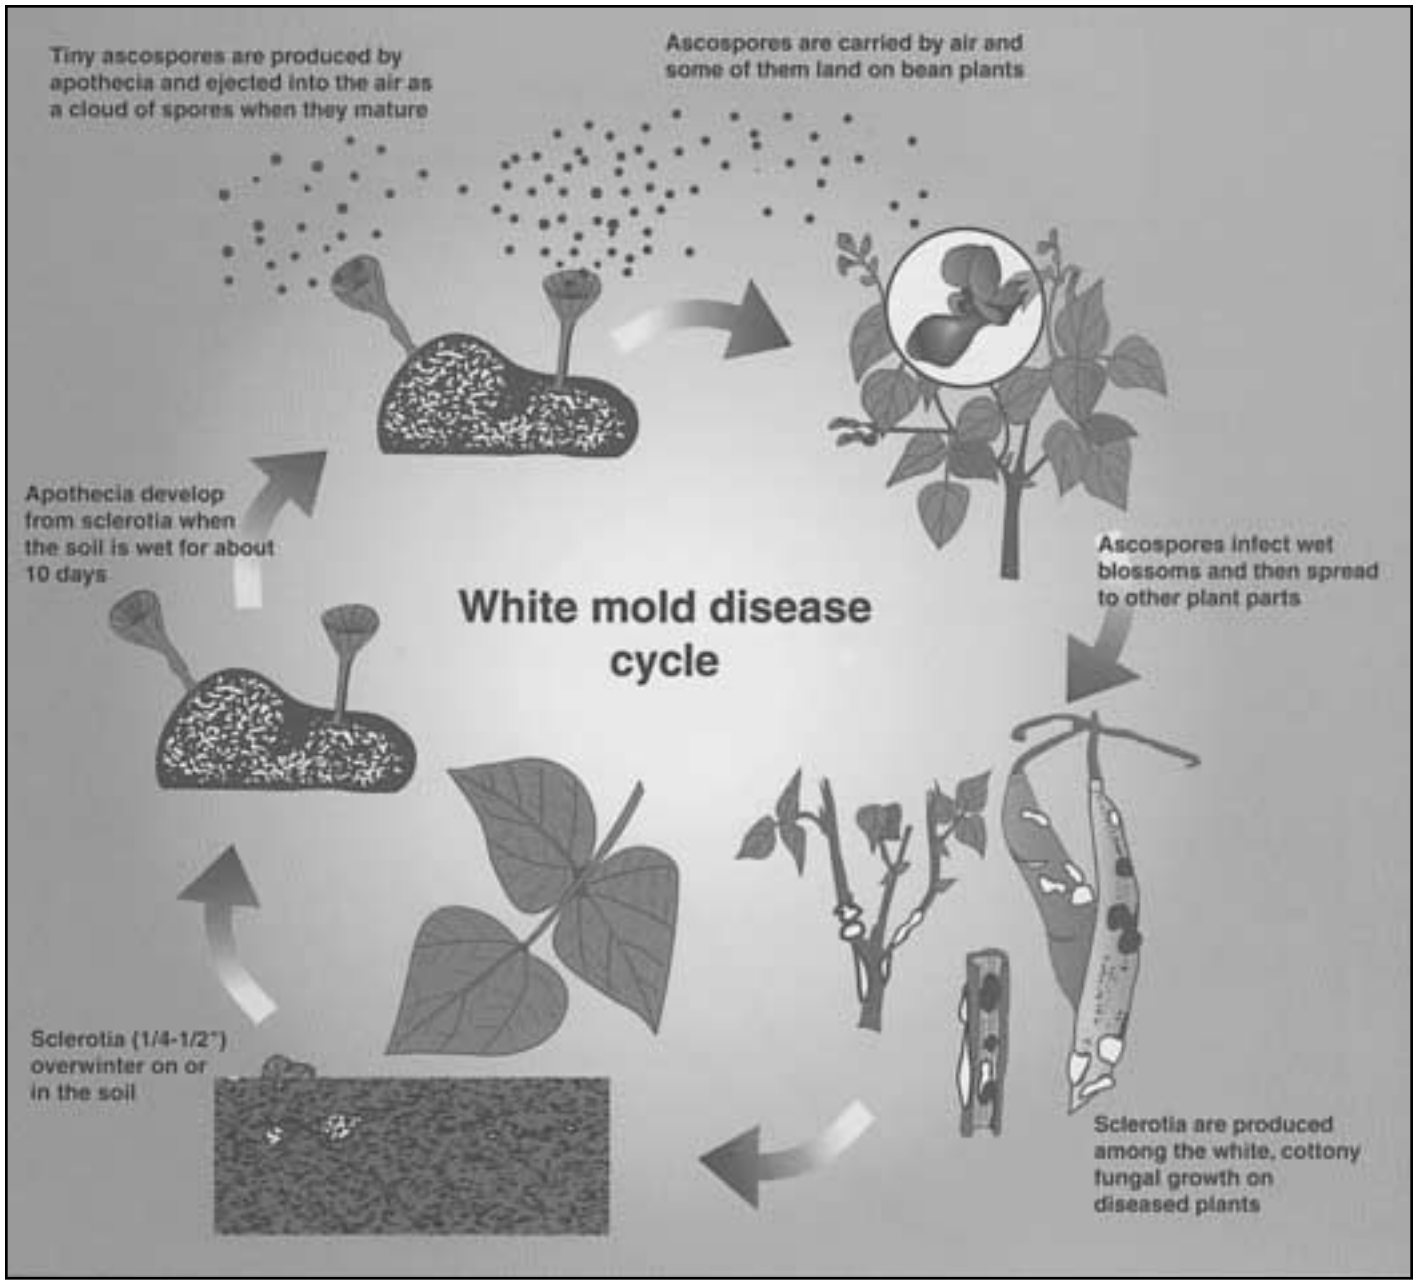
Fungi are the largest and most familiar group of plant pathogens. The best known fungi are mushrooms and yeast. Most fungi are extremely small and can not be seen without a microscope. Fungi can not convert sunlight into food and therefore feed on dead or decaying organic matter (for example, dead trees) or living matter (for example, corn and soybean plants).

Most fungi are made up of delicate, threadlike structures called **hyphae**. Hyphae grow and form masses called **mycelium**. The mycelium is the fuzzy growth that sometimes appears on the surface of a plant. Hyphae absorb nutrients and water needed for fungal growth and reproduction.

Most fungi reproduce by forming microscopic **spores**. Spores come in many shapes and sizes. Some spores are produced in structures called **fruiting bodies**. Others appear on the plant surface as mold growth (for example, powdery mildew, rusts, and blights). Each fungus has a unique spore or fruiting body structure. These are often used for identification.

Wind, splashing rain, insects, birds, workers' hands and clothing, and equipment easily transport spores from one location to another. Harsh environmental conditions will kill most spores; other spores can be dormant for several months or years before germinating.

Some fungi survive harsh environmental conditions by producing specialized structures, such as **sclerotia**. Sclerotia are masses of hyphae and food that can withstand long periods of extreme hot or cold temperatures and lack of water. When environmental conditions turn more favorable, the fungus again produces spores to infect hosts.



White mold disease cycle.

BACTERIA

Bacteria are very small, microscopic, one-celled organisms. Some bacteria are harmful to humans and animals because they cause diseases, such as pneumonia, tuberculosis, typhoid fever, and anthrax. Bacteria also cause disease in plants, but most bacteria are harmless or beneficial (for example, the nitrogen-fixing bacteria of legumes).

Bacteria enter plants through wounds or natural openings in the plant, usually in the leaf but sometimes roots and stems. Once inside the plant, bacteria begin to multiply rapidly. Bacteria live in the spaces between plant cells. The life cycle of a bacterium may be only 20 minutes, so a population of bacteria may increase rapidly.

Bacteria do not produce spores or fruiting bodies—they reproduce by simple cell division. A cell splits into approximately two equal halves. Each half forms a new fully developed bacterium. Bacteria, like fungi, rely on their host plant for food. In the absence of a host plant, a bacteria population may decline rapidly.

Bacteria are spread primarily by wind-driven rain, but driving through a field wet from dew will also spread bacteria. Insects spread some bacterial diseases, such as Stewart's wilt. Typical symptoms of bacterial disease include leaf spots, soft rot of tissues, and water-soaking of tissue.

Stewart's wilt is caused by a bacteria that is transmitted by corn flea beetles.

VIRUSES

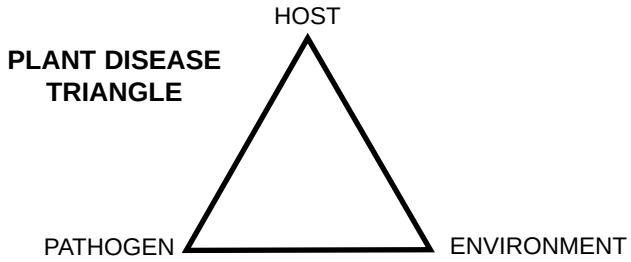
A **virus** is a very small non-living organism that cannot reproduce by itself. Viruses multiply by tricking the host cells into making more viruses. They are most familiar to us as the cause of human and animal diseases such as polio, influenza, chickenpox, and warts. Viruses can also cause diseases in plants.

Plants infected with a virus can show any of the following symptoms: yellow to dark green mottling, stunting of the leaves, early leaf fall, loss of plant vigor, mosaic patterns on leaves, deformation of plant tissues, and reduced yield. Sometimes a virus disease is mistaken for nutrient deficiency, pesticide or fertilizer injury, insect or mite activity, or other types of disease.

Because viruses can survive only in living cells, they need to enter a plant by means of a **vector**, usually an insect. Piercing-sucking insects, such as leafhoppers and aphids, are usually responsible for transmitting virus diseases. Pollen, soilborne fungi, or nematodes can transmit a few viruses. Viruses can also be transmitted by vegetative means, such as tubers, bulbs, and root cuttings. Sometimes they are a serious problem for crops that are propagated from cuttings (for example, potatoes and mint).

DISEASE TRIANGLE

Plant diseases occur when a pathogen attacks a susceptible plant under environmental conditions that favor infection and growth of the pathogen. Plant diseases are the result of a complex interaction between the plant, the pathogen, and the environment. This interaction is often represented graphically as the disease triangle. By changing any side of the disease triangle, such as adding an unfavorable environment or using a disease-resistant variety, you can reduce disease development.



The role of the environment in this interaction is important because pathogens need specific conditions to develop. If the environment is not suitable, a disease will not develop. Temperature and moisture are probably the two most important environmental conditions that influence plant diseases.

Air or soil temperature affects the growth of the host plant and / or the pathogen. If the host plant is stressed or grows poorly, it may be more susceptible to disease. Temperature may also change the speed of growth of a pathogen.

Pathogens and host plants are also affected by moisture. Fungal spores need moisture to germinate. A host plant experiencing moisture stress may be more susceptible to some pathogens. Also, many pathogens are spread by wind-blown rain or require moisture to infect the plant.

A successful disease management program takes into account the interactions between the environment, the disease, and the host plant. Disease management emphasizes reducing pathogen survival and limiting pathogen dispersal. For example, planting resistant varieties, improving soil drainage, or destroying or removing infected plants disrupts the disease triangle.

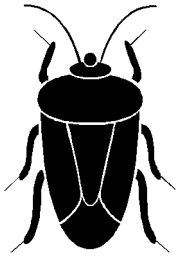
DISEASE CYCLE

All plant pathogens have a basic chain of events involved in disease development called the **disease cycle**.

The basic steps are:

1. **Production of inoculum. Inoculum** is a source of a pathogen that infects plants and causes a disease (for example, fungal spores, bacterial cells, and virus particles). Inoculum can be present in soil, seed, weeds, crop residue, or other crops, and/or carried by the wind, rain, insects, animals, people, and machinery.

2. **Spread of inoculum.** The inoculum must disperse to the host plant. There are two types of spore movement—active and passive. **Active movement** occurs when the inoculum is carried to a host by another organism (for example, insects or animals). One example is the spread of barley yellow dwarf virus (BYDV) from plant to plant by aphids.



Passive movement is movement of the inoculum to a new host plant by wind or water. Most fungal and bacterial foliar pathogens disperse this way.

3. **Infection.** Infection occurs when the plant pathogen becomes established in the host. A successful plant pathogen grows, spreads within the host plant, and produces new inoculum. As the pathogen grows in the host plant, symptoms begin to appear. The time period between infection and the appearance of the first symptoms is called the **incubation period**. An incubation period can be several days to months.

4. **Pathogen survival between susceptible crops.** In Michigan, pathogens need to survive the winter between growing seasons and periods when no host is present. Disease pathogens survive non-host periods by:

   a. Surviving on crop residues left in the field.

   b. Producing structures that resist microbial and environmental breakdown.

   c. Infecting seeds.

   d. Infecting alternate hosts. A pathogen with a large host range has an increased chance of survival. Some plant pathogens may survive in alternate hosts without causing disease.

DISEASE MANAGEMENT

Options for disease management in Michigan field crops are limited. The best available disease management strategies concentrate on preventing disease. Chapter 1 of this manual deals with general aspects of IPM. This section will address control options specific to diseases.

Cultural Control

Changing crop production practices can help reduce the incidence and impact of many field crop diseases. Cultural practices can disrupt the disease cycle, create unfavorable environmental conditions for the pathogen, reduce the pathogen population in the field, and improve crop growth and vigor.

1. CROP ROTATION. Many plant pathogens survive from one growing season to the next in the soil or on crop residues. To reduce disease, avoid planting the same crop in a field year after year. Alternating to non-host crops provides time to reduce pathogen populations. Some pathogens have a wide host range and are not affected by the sequence of the crop rotation. The fungus Sclerotinia sclerotiorum, responsible for white mold in soybeans, can also infect dry beans, potatoes, tomatoes, and canola. A rotation that includes two of these crops can increase the pathogen population faster than a rotation that includes only one host.

2. TILLAGE. Incorporating crop residues permits soil microorganisms to decompose the residue, prey directly on the pathogen, or outcompete the pathogen for resources. The result is a decrease in the pathogen population. Corn residues left on the soil surface, periods of high daytime temperatures, and high relative humidity are the favored growing conditions for the fungal pathogen Cercospora zeae-maydis, which causes corn gray leaf spot.

3. ROW SPACING. Soil moisture changes with row spacing. Wider row spacing allows the surface of the soil to dry out faster and increases the amount of time needed to create a closed row. For example, wider row spacing can reduce the incidence of white mold in soybeans and dry beans.

4. VARIETY SELECTION. The use of resistant varieties or hybrids is the least expensive, easiest, and most effective way to control plant diseases. Plant varieties express different degrees of resistance to many diseases. A resistant variety can act as a non-host crop for a specific pathogen. Partially resistant varieties may not prevent the spores of a pathogen from germinating and growing but may reduce the number of new spores produced. This helps keep the pathogen from reaching yield-reducing thresholds.

5. SEED QUALITY. Certified seed is high-quality seed that is selected from healthy, relatively disease-free plants. Certified seed is of known origin and genetic makeup and provides you with a genetically pure crop. Poor seed quality may be associated with fungal or bacterial pathogens that use seed for survival and dispersal. Plants infected with seed-transmitted pathogens should not be used for seed.

Biological Control

Controlling plant pathogens with other bacteria, fungi, or viruses is not very successful. Once disease has infected a field, there is little opportunity to use biological control. However, biological control can be successfully used on insect vectors and surrounding weeds that may serve as an inoculum for a pathogen. Rotation and tillage contribute to biological control by giving natural enemies time to reduce pathogen populations, even when the exact identity of the biological control agent is unknown.

Chemical Control

Chemical seed or foliar treatments are often used to control pathogens. Seed treatments can be an effective control for pathogens that live on and/or disperse by seed. For example, treating wheat seed with a systemic fungicide prevents the survival and spread of wheat loose smut (*Ustilageo tritici*), a fungal pathogen. Chemically treated seeds also protect against fungi living in the soil (for example, *Fusarium, Rhizoctonia, Pythium*). These fungi can cause seed and seedling death shortly after planting. Chemically treating dry bean, wheat, alfalfa, and corn seeds before planting helps prevent disease.

Though they're not economically feasible for many Michigan field crop situations, foliar pesticides can be used to control powdery mildew and rust on wheat, white mold in dry beans, *Cercospora* leaf spot in sugar beets, and a variety of diseases on seed corn. It is often much more difficult to control pathogens with pesticide applications than it is to control weeds or insects. The fact that pathogens live in close association with their host makes it difficult to kill the pathogen and not harm the host.

DISEASES OF ALFALFA

Phytophthora root rot

***Phytophthora* root rot in alfalfa.**

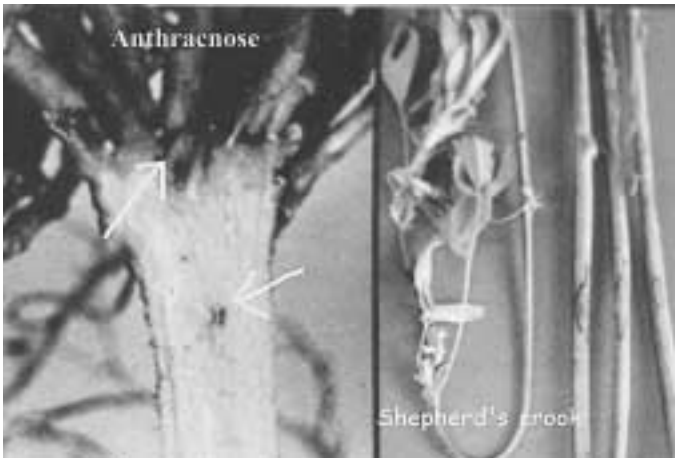
Pathogen type: fungus (Phytophthora megasperma)

Disease symptoms: The first signs of *Phytophthora* infections are dark brown lesions on the taproot. Infected plants will be stunted and yellow and may wilt and die. Phytophthora can also cause **damping-off**—when a seedling fails to emerge or collapses at the soil surface.

Environmental conditions favoring disease: *Phytophthora* is a soil fungus that becomes active after periods of excessive moisture. The pathogen grows best in poorly drained soils during periods of extensive rainfall, and young seedlings are the most susceptible.

Control: *Phytophthora* root rot yield losses can be minimized by improving soil drainage. Planting *Phytophthora* resistant varieties and treating seeds with fungicide can also help reduce the number of plants lost from damping-off.

Anthracnose



Alfalfa infected with anthracnose.

Pathogen type: fungus (*Collectotrichum trifolii*)

Disease symptoms: An alfalfa plant infected with the anthracnose fungus has diamond-shaped lesions near the base of the stem. The lesions are tan with dark brown borders and contain small, black fruiting bodies. Infected stems wilt, producing the characteristic "shepherd's crook" symptom. When alfalfa crowns are invaded, the inner tissues turn bluish black and the plant dies.

Environmental conditions favoring disease: Anthracnose is a warm, humid weather disease. The spores are spread by wind and splashing rain.

Control: The best control option for anthracnose is to plant resistant varieties. Foliar fungicides are not registered for alfalfa.

Crown Rot

Pathogen type: several species of fungus

Symptoms: The crown discolors, turning tan to black. Rotten tissue intersperses with healthy tissue. Slowly, the crown dies. Alfalfa stands gradually begin to thin.

Environmental conditions favoring disease: Fungal spores enter the alfalfa plant through wounds in the roots caused by environmental, mechanical, or insect damage. Therefore, this disease can occur under any environmental conditions that favor root damage.

Control: Minimizing traffic over the field reduces crown damage. Maintain plant vigor, monitor soil levels of potassium (K+), and practice a two-year crop rotation out of small grains.

DISEASES OF CORN

Corn Gray Leaf Spot

Pathogen type: fungus (*Cercospora zeae-maydis*)

Disease symptoms: Long, rectanglar lesions appear on the leaf surface. Lesions are $^1/_2$ to 4 inches long and tan to gray.

Environmental conditions favoring disease: The fungus causing corn gray leaf spot lives in crop residue left on the soil surface. The fungus grows best under high daytime temperatures (above 85 degrees F) and relative humidity (above 90percent).

Control: Eliminating infected surface crop residue and rotating crops help control the fungus. Fungicides are used effectively in seed corn.

Common Rust

Close-up of leaf rust.

Pathogen type: fungus (*Puccinia sorghi*)

Disease symptoms: Oval or elongated brick-red blisters appear on the leaf surfaces. Rust can kill the leaves of young plants.

Environmental conditions favoring disease: Rust occurs every year, usually late in the season. Rust develops on bright days with cool temperatures (60 to 73 degrees F) and high humidity. The fungal spores are dispersed by the wind.

Control: Planting resistant hybrids is the best way to control rust. Fungicides are used effectively in seed corn.

Gibberella Stalk and Ear Rot

Corn stalk of a *Gibberella* infected plant.

Pathogen type: fungus (*Gibberella* spp.)

Disease symptoms: Gibberella can cause both stalk and ear rot. When the fungus attacks the cornstalk, it often becomes soft and turns brown. The inside of the stalk shreds and turns pink to reddish. The interior of the stalk rots, and the stalk can be easily broken. The usual result is excessive plant lodging.

Gibberella ear rot is caused when the fungus enters the ear through the silk. As the fungus grows, it produces a white-pinkish mold on the ear tip. The fungus may not grow into large molds. *Gibberella* can produce a toxin, **vomitoxin**, that makes the grain unfit for feeding to livestock or humans.

Environmental conditions favoring disease: *Gibberella* stalk rot prefers dry conditions early in the season followed by warm, wet weather two to three weeks after silking. *Gibberella* ear rot develops best when the weather is cool and wet within three weeks of silking. The fungal spores overwinter in the soil and corn debris and are transported by the wind.

Control: Planting corn hybrids that have been selected for resistance to *Gibberella* is the most effective control method. Hybrids with tight husk coverage may have reduced rates of ear rot infection. Also, an early harvest and proper storage may reduce the possibility of ear rot infection. Healthy plants are less susceptible to stalk rot.

Corn Smut

Pathogen type: fungus (*Ustilago maydis*)

Disease symptoms: Galls are formed on aboveground young growing parts of the plant—typically, the ear, tassel, leaves, and stalk. The young galls have a greenish white covering that turns silver-gray as they age. A mature gall is full of black, powdery fungal spores. The spores are dispersed into the air when the gall ruptures.

Environmental conditions favoring disease: Corn smut is most prevalent in warm and moderately dry areas. Galls are more likely to occur under dry conditions and temperatures of 78 to 94 degrees F. The smut fungus favors stressed plants. The fungal spores overwinter in the soil and prefer high levels of soil nitrogen.

Smut on ear.

Control: The best management strategy is to plant corn hybrids with some level of resistance. Rotating crops and burying crop residue also offer some control of the fungus.

DISEASES OF DRY BEANS

Dry Bean Halo Blight

Dry bean halo blight on leaves.

Pathogen type: bacterium (*Pseudomonas syringae*)

Disease symptoms: The leaves and/or pods have water-soaked marks. Surrounding each mark is a broad light green or yellow halo. The halo can be as big as a dime to the size of a quarter. Early pod infection causes the seeds to shrivel.

Environmental conditions favoring disease: The bacterium prefers cool weather. The pathogen is spread by splashing rain and workers and machinery moving in an infected field with wet plants. It survives on crop residue from season to season.

Control: Seed treatment controls surface contamination but not internal contamination. All seed should be blight tested at the Michigan Department of Agriculture lab. Any seed testing positive should not be used. The disease usually stops developing under warm temperatures. Resistant varieties and seed treatments help reduce the possibility of infection. All navy bean varieties are resistant to halo blight. Yearly infections can be prevented by removing crop residue and by practicing a crop rotation of two or more years. The bacteria spread can also be reduced by minimizing work in fields when the plants are wet.

Common Blight

Common blight in dry beans.

Pathogen type: bacterium (*Xanthomonas campestris*)

Disease symptoms: Leaves and pods have small, water-soaked spots that merge together and turn brown. Unlike halo blight, common blight has only a narrow, bright yellow margin around each spot. The water marks become dry, red-brown spots on infected pods.

Environmental conditions favoring disease: Common blight is more common in warm weather. The pathogen survives in infected seed and on crop residue. Bacteria are spread among plants and fields by splashing rain and people and machinery moving in the field when plants are wet.

Control: Seed treatment controls surface contamination but not internal contamination. All seed should be blight tested at the Michigan Department of Agriculture lab. Any seed testing positive should not be used. Yearly infections can be prevented by removing crop residue and by practicing a crop rotation of two or more years. To reduce the spread of bacteria, minimize work in fields when plants are wet. There are no varieties resistant to common blight.

Fusarium Root Rot

Fusarium root rot infected dry beans.

Pathogen type: fungus (*Fusarium solani* f. sp. *phaseoli*)

Disease symptoms: Two to three weeks after planting, reddish brown streaks appear on the seedling's stem. The lesions may extend upward to the soil surface and turn brown with age. Plants appear stunted with yellow leaves but seldom die.

Environmental conditions favoring disease: Early planting in cool, moist soil favors Fusarium root rot. Any condition that reduces root growth increases the likelihood of infection. The pathogen lives in the soil and can survive for years.

Control: The disease causes little damage to healthy plants. Therefore, the best control against Fusarium root rot is to maintain a healthy crop. Plant in late May or early June to avoid unfavorable soil conditions. A three-year crop rotation out of beans reduces the chances of infection. Varieties differ in resistance.

DISEASES OF SOYBEANS

Phytophthora Stem and Root Rot

Pathogen type: fungus (*Phytophthora sojae*)

Disease symptoms: The fungus can attack a plant at any growth stage, including seed. Infected seeds often die before they emerge. The fungus commonly destroys the plant at the soil level, causing the seedling or plant to fall over. This is called **damping-off**. If the plant is stressed, the disease can cause sudden wilting and drying of leaves. The roots and stems may also turn brown. Older infected plants were usually infected when they were seedlings. They may be stunted and eventually die.

Environmental conditions favoring disease: Periods of high soil moisture, rainfall, or standing water favor the development of the disease. The disease is found more frequently in heavy soils with poor drainage and areas with high rainfall. The fungus overwinters in the soil as spores. The spores are dispersed by the wind.

Phytophthora stem and root rot in soybeans.

Control: Use farming practices that reduce soil compaction, increase soil aeration, and improve soil structure. Avoid planting in poorly drained soils. Plant resistant hybrids. There is more than one race of *Phytophthora sojae*, and not every resistant hybrid is an effective control for every race of the pathogen. Check with your county Extension agent for information about resistant soybean varieties for your area.

White Mold

Pathogen type: fungus (*Sclerotinia sclerotiorum*)

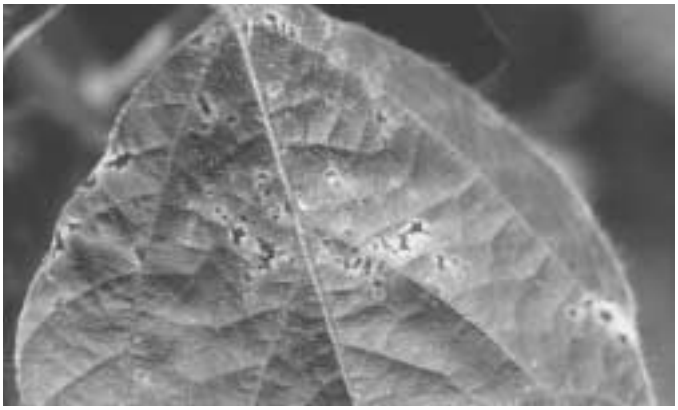
Disease symptoms: Fungal spores enter the plant **only** through the flowers. A fluffy, white mold grows on nodes and stems. Leaves wilt and turn brown. This growth can girdle the stem, killing the plant. Dead plants stay erect. Hard, black fungal bodies (sclerotia) develop in and outside of the stems and pods. These fungal bodies can be harvested with the soybeans, returned to the soil, or moved around the field or from field to field to reinfect the following season.

Environmental conditions favoring disease: Wet weather two weeks before and during flowering of the soybean plant is important for infection. The capacity of the soybean canopy to keep stems wet for extended periods of time contributes to disease severity.

Soybeans killed by white mold (X. B. Yang, Iowa State University).

Control: Planting wider rows allows the soil to dry out. This changes the environmental factors necessary for the pathogen to infect the soybean plant. Preventing the introduction of the pathogen by thoroughly cleaning equipment can minimize the spread of white mold between fields. The severity of white mold infections can be reduced by long crop rotations. However, the fungus attacks other field crops, including dry beans and vegetables such as tomatoes, potatoes, canola, and cucumbers. Therefore, alternate white mold-susceptible crops in rotations with corn or wheat to reduce fungal survival. Check with your county Extension agent for information on chemical control of white mold.

Septoria Brown Spot



Septoria brown spot infected soybeans.

Pathogen type: fungus (*Septoria* spp.)

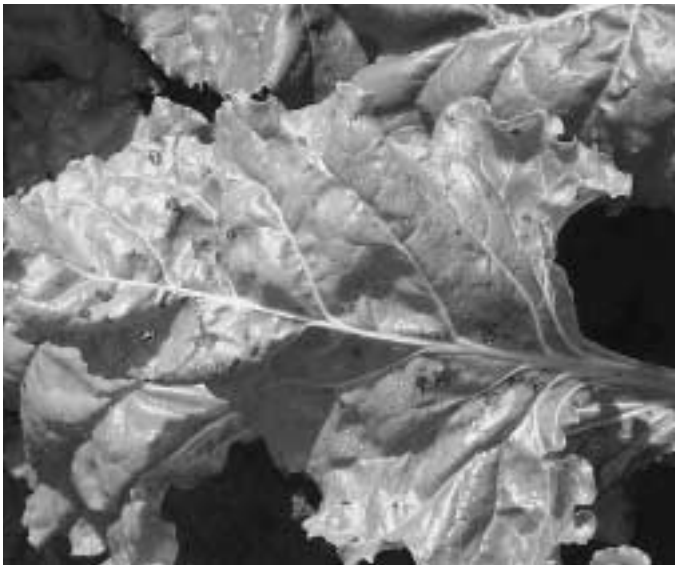
Disease symptoms: Irregular, dark brown spots that vary from minute flecks to lesions $^{3}/_{16}$ inch in diameter form on the leaves. The spots may have yellow borders. The symptoms usually appear on the lower leaves first. Eventually, the leaves drop off.

Environmental conditions favoring disease: Wet conditions with heavy rain spread the fungus upward in the plant canopy. The fungus attacks young seedlings early and late in the season. The spores overwinter in the soil and are dispersed by the wind.

Control: There is little to no economic loss from brown spot, so no control options are recommended. Continuous cropping of soybeans may increase the severity of the disease, however.

DISEASES OF SUGAR BEETS

Cercospora Leaf Spot



Cercospora leaf spot in sugar beets.

Pathogen type: fungus (*Cercospora beticola*)

Disease symptoms: Small, brown spots with purple borders appear on leaves and leaf stems. The spots merge, causing the leaves to turn yellow to brown. In high humidity and heavy dew, the spots look gray. Finally, the leaf collapses but remains attached.

Environmental conditions favoring disease: The fungus survives on crop residue and develops best in high temperatures and high humidity.

Control: Crop rotation and clean plowing to reduce crop residue diminish pathogen infection from year to year. Planting disease-tolerant varieties also reduces fungal infections. Foliar fungicides are effective and can be used even on disease-tolerant varieties.

Black Root

Pathogen type: Several fungi cause black root, but the most serious one is *Aphanomyces cochloides*.

Disease symptoms: The fungus infects the seedling roots. Brown, water-soaked regions appear on the stem and cotyledons. The infected root and stem turn black and become threadlike. Damping-off usually occurs.

Environmental conditions favoring disease: This soilborne fungus prefers warm, wet soils.

Control: Seed treatments and tolerant varieties offer control. Also, planting on well drained soils will decrease the disease, which prefers wet areas of the field—for example, near drainage ditches and low spots. Crop rotation is also an effective control.

Rhizoctonia Root Rot

Pathogen type: fungus (*Rhizoctonia solani*)

Disease symptoms: Sudden wilting, leaf stems turning black, and outer leaves yellowing are the first symptoms. The wilted leaves collapse and die. The roots may partially or completely rot. Infected areas on the root surface are dark brown to black.

Environmental conditions favoring disease: This is a common soil fungus that attacks a wide host range. Rhizoctonia root rot prefers high temperatures and is more severe in heavy, poorly drained soils.

Control: Rhizoctonia root rot is difficult to control. Tillage, fertilizing, promoting healthy plants and good soil drainage, practicing crop rotation, and controlling weeds all help reduce the occurrence of this disease.

DISEASES OF WHEAT AND SMALL GRAINS

Wheat Scab

Scab causes premature ripening of wheat (G. Munkvold, Iowa State University).

Pathogen type: fungus (*Fusarium graminearum*)

Disease symptoms: Infection occurs at flowering, and infected spikelets will have a bleached appearance. Orange or pink spore masses can be found at the bases of the spikelets. The fungus enters the kernels, turning them light brown to pink when infections occur early in the season. Infected kernels may be shrunken, wrinkled, and lightweight, though many infected kernels show no symptoms. The fungus produces vomitoxin, a toxin that can cause vomiting, nausea, dizziness, and diarrhea in non-ruminant animals such as humans and hogs. The chance of vomitoxin getting into human food is slim because grain is tested. However, problems may develop from feeding livestock uncleaned, scabby wheat, oats, or barley. Hogs fed 10 percent or more scabby grain may vomit and refuse to eat the grain mixture. Vomitoxin does not break down easily and can remain in stored grain for a long time.

Environmental conditions favoring disease: The fungus develops in cool to moderate, wet weather during flowering and grain ripening. Periods of rain immediately before flowering and lasting for three or more days after flowering begins are highly favorable for scab development. The wind disperses spores that overwinter in infected grain and corn residue.

Control: Scab-infected seeds should not be used. Seed treatment will reduce seedling diseases but does not affect infection at flowering. The same fungus that causes wheat scab also causes stalk rot in corn. Therefore, plant away from old cornfields and avoid rotating wheat, corn, barley, oats, or rye into corn. Plant two or more varieties that flower three to seven days apart to reduce the risk of scab.

Wheat Yellow Mosaic Virus

Pathogen type: virus

Disease symptoms: Young leaves have light green or yellow streaks and dashes. Older leaves may be bright yellow-green. The leaf markings are parallel with leaf veins and taper at both ends to form spindles. Wheat yellow mosaic virus-infected plants tend to be uniformly distributed throughout the field. Infected plants produce fewer tillers, smaller heads and less seed per head than healthy plants. Plants may be mildly stunted, but this is not often evident.

Environmental conditions favoring disease: Cold air temperatures (40 to 50 degrees F) favor infection by this virus. Generally, as temperatures warm, the plant appears to have outgrown the virus. In years with prolonged cool temperatures, susceptible varieties can display symptoms through early June.

Method of transmission: The virus survives in the soil and is transmitted to plants by a soilborne fungus, *Polymyxa graminis.* Cultivating equipment, wind, water, and other factors that disperse infested soil spreads wheat yellow mosaic virus. Soils may remain infected for years.

Control: Resistant varieties and long crop rotations with legumes reduce the potential for wheat yellow mosaic virus infections.

Barley Yellow Dwarf Virus

Barley yellow dwarf virus in wheat, with healthy plants on the left (G. Munkvold, Iowa State University).

Pathogen type: virus

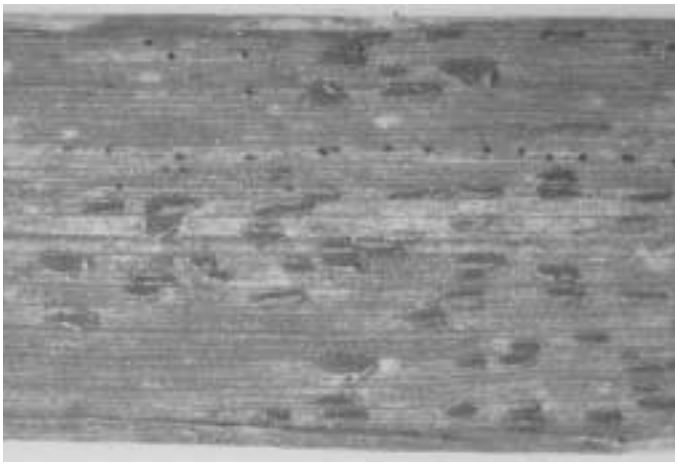
Disease symptoms: Starting at the leaf tip, leaves turn yellow or bright red. Infection in young plants may cause stunting. Plants can be attacked in both the fall and spring. Plants infected in fall may be unable to survive the winter. Spring infections may result in discoloration of only the top leaf (flag leaf). Distribution of the virus in the field depends on the aphid population.

Environmental conditions favoring disease: Moderate temperatures favor foliar symptoms. Barley yellow dwarf virus epidemics occur when the weather conditions favor the aphid vectors. Cool (50 to 65 degrees F), moist weather is most favorable. Aphid movement can be local, from one field to another, or aphids can be carried hundreds of miles by the wind. Generally, aphids migrate from the southern states to the northern states in spring and from north to south in fall.

Method of transmission: More than 20 species of aphids are known to transmit the virus, which exists as several strains. Several aphids transmit some strains of the virus equally well, whereas other strains can be transmitted by only one or two aphid species. All cereals and wild grasses are hosts.

Control: Resistant oat varieties are available. Barley and wheat varieties show differences in barley yellow dwarf virus infections, but they are not resistant. Plant winter wheat five to 10 days after the Hessian fly-free date and barley as late as practical to avoid early fall infections. Plant spring oats as early as possible. Vigorously growing plants are more tolerant of barley yellow dwarf virus. Control volunteer wheat, barley and oats—they can serve as reservoirs of the virus. Chemical control of the aphid vectors is not effective or economical.

Leaf Rust



Leaf rust pustules on wheat (G. Munkvold, Iowa State University).

Pathogen type: fungus (*Puccinia recondita*)

Disease symptoms: Small, round or oval, raised, orange-red blisters or pustules appear on leaf surfaces. They can be either scattered or clumped on the leaf surface. Each pustule contains thousands of spores. Rubbing the pustules and releasing the spores confirms the identification of rust.

Environmental conditions favoring disease: Cool nights and warm, bright days. The stems and leaves need to be moisture free for six to eight hours.

Method of transmission: Fungal spores are windblown. New infections can occur every 10 to 12 days.

Control: Plant resistant varieties. Fungicides can be effective for early-season infections.

General Control Practices for All Wheat and Small Grain Diseases

1. Select varieties that are high yielding and resistant to the major diseases.
2. Plant more than one variety. Planting varieties that flower at different times helps to reduce the incidence of scab.

3. Treat all seeds before planting. This is a must for any wheat grown in Michigan. Seed treatments reduce infections by seedborne pathogens such as wheat scab and are critical to control loose smut and common (stinky) smut.
4. Scout fields beginning in mid-May to identify fields that are potential problems. Remember to scout the entire field to locate pockets of infection.
5. Protect the flag leaf. Eighty percent of the yield comes from the flag leaf. Chemical treatments should not be applied until the flag leaf has emerged and only in conjunction with scouting. Fungicides are not labeled for application after flowering.

Review Questions

Chapter 7: Disease Management

Write the answers to the following questions and then check your answers with those in the back of the manual.

1. Which of the following can cause a non-infectious disease?
   A. Drought
   B. Insects
   C. Viruses
   D. Bacteria

2. An organism that causes disease is a:
   A. Parasitoid.
   B. Predator.
   C. Pathogen.
   D. Parasite.

3. Infectious plant diseases can be spread from diseased plants to healthy plants.
   A. True
   B. False

4. Which of the following is a living microscopic one-celled organism?
   A. Virus
   B. Fungus
   C. Bacterium
   D. Fruiting body

5. Which of the following uses spores to reproduce?
   A. Virus
   B. Bacterium
   C. Fungus
   D. Nematode

6. Draw a picture of the disease triangle and label its three parts.

7. By changing an environmental factor such as soil moisture, you can influence plant diseases.
   A. True
   B. False

8. List the four basic steps of the disease cycle.

9. A plant pathogen that is dispersed by wind to unaffected plants is said to move by:

   A. Active movement.

   B. Passive movement.

10. The source of a plant pathogen that causes a disease is called a(n):

   A. Infection.

   B. Parasite.

   C. Inoculum.

   D. Host.

11. The time period between infection and appearance of the first plant symptoms is the:

   A. Preharvest interval.

   B. Restricted entry interval.

   C. Incubation period.

   D. Disease period.

12. Cultural control methods can disrupt the disease cycle by:

   A. Creating unfavorable conditions.

   B. Improving crop growth.

   C. Reducing the plant pathogen population in a field.

   D. All of the above.

13. Which of the following is NOT a cultural control?

   A. Planting high-quality seed.

   B. Treating seeds with a fungicide.

   C. Increasing the row spacing.

   D. Practicing crop rotation.

14. Biological control is the most effective tactic to use to control plant pathogens.

   A. True.

   B. False.

15. Which of the following alfalfa diseases causes the stems to take on a “shepherd’s crook” shape?

   A. Phytophthora root rot.

   B. Crown rot.

   C. Anthracnose

   D. Verticillium wilt.

16-19. Match the following corn disease with the characteristic disease symptoms.

   A. Gibberella stalk and ear rot

   B. Corn smut

   C. Common rust

   D. Corn gray leaf spot

   16. ___ Forms galls that usually appear on the ear.

   17 ___ Produces a pinkish mold.

   18. ___ Leaves have dark red blisters.

   19. ___ Fungus produces long, gray lesions on leaf surfaces.

20. Which of the following plant diseases is transmitted by aphids from an infected plant to a non-infected plant?

   A. White mold.

   B. Common rust.

   C. Corn smut.

   D. Barley yellow dwarf virus.

21-26. Match the following diseases with the type of plant pathogen that causes them.

   A. Bacterium

   B. Fungus

   C. Virus

   21. ___ Septoria brown spot

   22. ___ Common blight

   23. ___ Fusarium root rot

   24. ___ Wheat yellow mosaic

   25. ___ Dry bean halo blight

   26. ___ Anthracnose

27. The plant pathogen that causes white mold in soybeans enters the plant through the soybean _____.

   A. Stem.

   B. Root.

   C. Flower.

   D. Leaf.

28. Damping-off in soybeans can be caused by which plant disease?

   A. Septoria brown spot

   B. Fusarium root rot

   C. Phytophthora stem and root rot

   D. Common blight

29. More than one type of fungus can cause black root disease in sugar beets.

    A. True.

    B. False.

30. Wheat kernels that produce vomitoxin have been infected with:

    A. Wheat scab.

    B. Leaf rust.

    C. Wheat yellow mosaic virus.

    D. Barley yellow dwarf virus.

31. Vomitoxin is poisonous to humans.

    A. True.

    B. False.

32. Wheat yellow mosaic virus is transmitted to plants by:

    A. Insects.

    B. Fungi.

    C. Wind.

    D. None of the above.

33. Your barley plants have small, orange-red, round blisters or pustules on the leaves. When you rub the sores, lots of little specks or spores are released. Your barley plants are infected with which disease?

    A. Barley yellow dwarf virus

    B. Leaf rust

    C. Wheat yellow mosaic virus

    D. Wheat scab

34. List three common practices used to control small grain diseases.

CHAPTER 8

NEMATODE MANAGEMENT

LEARNING OBJECTIVES

After completely studying this chapter, you should:

- Know what a nematode is and how it develops.
- Know the three groups of control tactics specific to nematode management.
- Understand the life cycle and management options for soybean cyst nematode, sugar beet cyst nematode, corn needle nematode, the root-lesion nematode, and the northern root-knot nematode.

INTRODUCTION

Nematodes are very small roundworms. They live everywhere—in soil, plants, water, and animals, including humans. Nematodes feed on bacteria, fungi, algae, plants, and animals. A few thousand species attack plants; most nematodes feed on dead or decaying organic matter. Many nematode species are beneficial because they feed on bacteria, insects, fungi, and other soil pests.

The life cycle of a nematode is egg, four juvenile stages, and adult. Adult females lay eggs that hatch into young nematodes, **juveniles**. Juveniles look like small adults. First and second stage juveniles are usually found still inside the egg case. For most plant-parasitic nematodes, egg hatching takes place during the second juvenile stage. After a total of four molts (shedding of their skin), the juveniles become adults. If males and females are present, they mate and produce more eggs. Typically, the life cycle of a plant-parasitic nematode is completed within 20 to 60 days.

About 95 percent of plant-feeding nematodes live in the soil and feed in or on roots. Some consume aboveground plant parts. Plant-feeding nematodes feed by inserting a needlelike structure (**stylet**) into plant cells. They inject an enzyme into the cell that dissolves the cell contents. The nematode then uses its stylet like a straw to remove the liquid cell contents.

Nematode root feeding directly interferes with a plant's ability to take up water and nutrients. Infected plants wilt and appear to be suffering from a lack of water or nutrients. These symptoms can easily be mistaken for damage caused by other conditions. High nematode populations result in plant stunting, yellowing, a general decline in plant health, and sometimes plant death. Nematode feeding can cause yield loss. The feeding sites also act as points of entry for other pathogens such as fungi and bacteria.

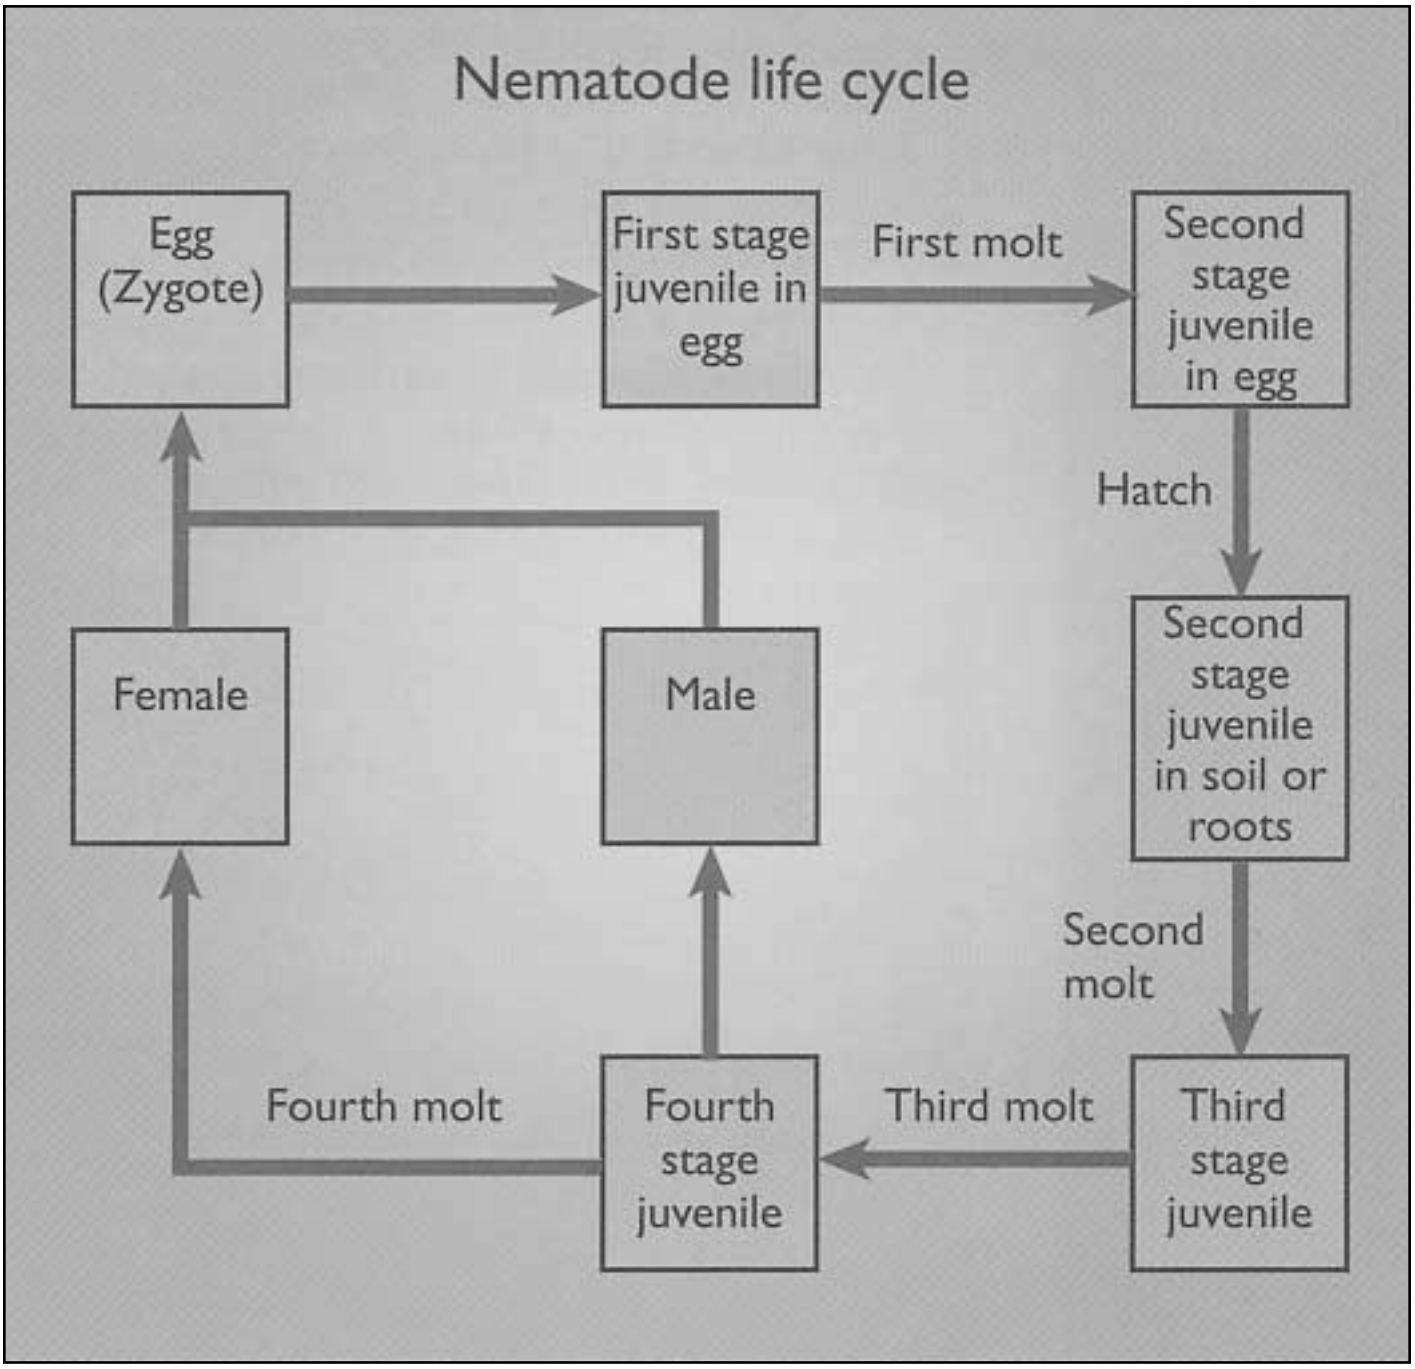
Though nematodes are small, they can easily disperse over long and short distances. In the soil, nematodes move approximately 1 inch per year. However, they can be transported from field to field or within a field by flood waters, dust storms, contaminated machinery, and nursery stock or transplants.

Nematode populations are identified and located from field soil samples. Soil and root samples can be submitted to MSU Diagnostic Services for identification. After proper identification, a site-specific nematode management program can be developed. Details on how to collect and submit a proper soil sample are found in current MSU Extension bulletins.

NEMATODE MANAGEMENT

Nematode management tactics can be grouped into three types: prevention, containment, and chemical control.

- **Prevention tactics** are intended to prevent nematode problems. Some are: practicing crop rotation, using nematode-free seeds and transplants, planting nematode-resistant or -tolerant varieties, keeping farm equipment nematode free, and maintaining good farm sanitation.



Nematode life cycle.

- **Containment tactics** keep a nematode population from spreading to other fields or other areas in the same field. It is nearly impossible to completely remove a nematode population from a field after it has become established. Prevention tactics such as crop rotation and planting nematode-free seeds and transplants can reduce the nematode population, however.
- **Chemical control tactics** are not often recommended for nematode control. However, both fumigant and non-fumigant nematicides (nematode-specific pesticides) are available. Chemical control of nematodes should always be used in conjunction with other nematode management strategies. For pesticide recommendations, refer to current MSU Extension bulletins.

SOYBEAN CYST NEMATODE

Host plants: Soybeans, dry beans, and other legume crops (green beans, green peas) and weeds (henbit, field pennycress, shepherd's purse).

First detection in Michigan: 1987.

Life cycle: The adult female soybean cyst nematode mates with a male and produces 150 to 500 eggs. Shortly after mating, she dies. But first she deposits a few eggs on the outside of her body. The other eggs remain in her dead body, which is called a **cyst**. In the cyst the eggs are protected from predators and environmental factors that would kill them. The eggs in the cyst hatch over the next eight years. Soybean cyst nematode eggs survive best

Soybean cyst nematodes on soybean roots (G. Tylka, Iowa State University).

under cool, moist conditions. The juveniles emerge from the eggs and immediately begin searching for food -- soybean roots. Once the juveniles find a soybean root, they enter the root and begin to feed. A juvenile soybean cyst nematode molts four times before becoming an adult nematode. Under moderate soil conditions, it takes 21 to 24 days for a soybean cyst nematode to complete its life cycle.

Soybean field infected with soybean cyst nematodes.

Damage and symptoms: The most common aboveground symptoms of soybean cyst nematode damage are stunted and yellowed plants. Plant symptoms are usually not evenly distributed in a field. In early July, white female soybean cyst nematodes are found attached to plant roots. As the nematodes age, they become yellow. The attached females are the only visible sign of a soybean cyst nematode infestation. Soybean cyst nematode infestations can reduce soybean yields by 30 percent without plants showing symptoms. Severe infestations can reduce soybean yields as much as 80 percent.

Management options: To prevent soybean cyst nematode infestations, practice crop rotation, plant nematode-free seed, and maintain clean machinery. Nematode-resistant and -tolerant soybean varieties are available. Fields with low to moderate soybean cyst nematode populations can be managed by practicing a three-year crop rotation. Longer rotations may be necessary for fields with large soybean cyst nematode populations. Soil fumigants are available but very expensive. Non-fumigant nematicides applied at planting may reduce soybean cyst nematode populations. In many situations, they, too, are very costly.

SUGAR BEET CYST NEMATODE

A sugar beet infected with sugar beet cyst nematode.

Host plants: Sugar beets, cabbage, mustard, cauliflower, and many weeds.

First detection in Michigan: 1949.

Life cycle: All cyst nematodes develop in the same manner. Therefore, the sugar beet cyst nematode is very

similar to the soybean cyst nematode. After hatching, the second stage juvenile (J2) nematodes enter the sugar beet roots to feed. As the nematode grows, it bursts from the root. The white to yellow adult females are exposed on the root surface. With ideal soil conditions, the sugar beet cyst nematode completes its life cycle in 25 days.

Plant symptoms of a sugar beet cyst nematode infestation.

Damage and symptoms: Typically, the sugarbeet cyst nematode is found in the fibrous roots, but it can also feed on the storage root. Infected sugar beet plants are stunted, have yellow foliage, and wilt in warm weather. The wilting can be persistent even in soil with high moisture levels. You can see female sugar beet cyst nematodes on the plants roots without a hand lens. Severe nematode infestations may reduce yields.

Management options: Sugar beets are the only major host of sugarbeet cyst nematodes in Michigan, so crop rotation provides sufficient control. Typically, at least a three-year rotation out of sugar beets is recommended. However, in heavily infested fields a longer rotation (five to eight years) may be necessary. Currently, there are no sugar beet varieties that are resistant to the sugar beet cyst nematode.

CORN NEEDLE NEMATODE

A corn needle nematode infestation can stunt a plant's growth.

Host plants: Corn and other grass plants

First detection in Michigan: 1980.

Life cycle: Female corn needle nematodes produce roughly one egg per day over several months. In the spring after the eggs hatch, the juvenile nematode feeds on young corn roots. As the soil temperature increases, the corn needle nematode migrates deeper into the soil and may stop feeding. In Michigan, it completes approximately one generation per year. The corn needle nematode is typically found in sandy fields with long histories of corn production and poor crop rotation. Unlike cyst nematodes, the corn needle nematode will not survive long without its host plant.

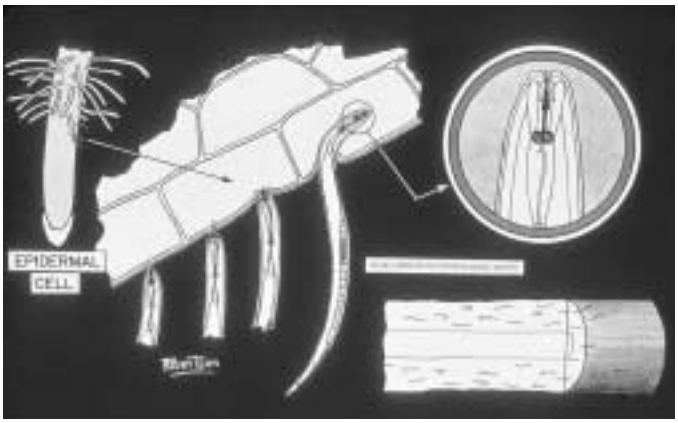
Damage and symptoms: Corn needle nematodes do not enter the root but feed close to the root tip, preventing the root from developing normally. The damage includes root tip swelling, stunted plants, small and barren ears at harvest, and a reduction (10 to 75 percent) in grain yields. The corn needle nematode prefers to live in coarse-textured or sandy soils. As the soil moisture decreases and temperature increases, the corn needle nematode moves deeper into the soil. During the summer, the corn needle nematode can be found 18 to 36 inches below the soil surface.

Management options: Soil sampling should be done in spring or fall, when the corn needle nematode is close to the soil surface. Sampling in the root zone during the summer will not detect it. Crop rotation, especially with soybeans or alfalfa, will reduce corn needle nematode populations. It is also important to maintain soil quality. Non-fumigant nematicides do not provide control of corn needle nematode.

ROOT-LESION NEMATODE

Host plants: More than 350 recorded host plants, including corn and sugar beets

First detection in Michigan: Unknown



Root lesion nematode.

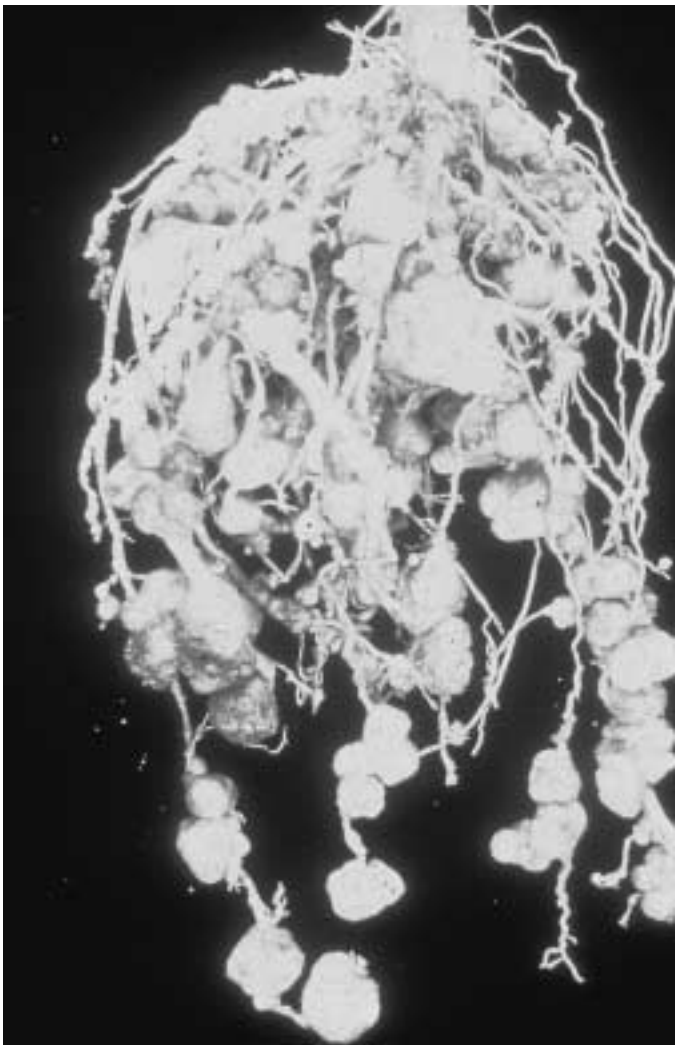
Life cycle: After mating, females lay single eggs in roots or soil. Second stage juveniles (J2) hatch from the eggs. Like all nematodes, the root-lesion nematode goes through four molts before reaching the adult stage. Adults and the last three juvenile stages can enter the roots to feed at any time. Root-lesion nematode may take from 30 to 86 days to complete its life cycle.

Damage and symptoms: Root-lesion nematodes usually feed on the smaller plant roots, killing them. The feeding sites allow other pathogens such as fungi and bacteria to enter the root system. Root-lesion nematode infestations cause plants to grow poorly and have yellow leaves that may wilt in hot weather, and can reduce crop yields. Infested seedlings are often stunted.

Management options: Root-lesion nematodes can attack a wide number plants. Therefore, crop rotation will usually not sufficiently reduce their populations. Nematicides are available but should always be used on a field-by-field basis and with a nematode management program.

NORTHERN ROOT-KNOT NEMATODE

Host plants: More than 300 recorded plants, including dry beans, soybeans, sugarbeets and forage legumes



Root-knot nematode.

First detection in Michigan: Early 1900s

Life cycle: The female northern root-knot nematode produces as many as 500 eggs. She carries these eggs in a slime like mass on the outside of her body. In early spring, second stage juveniles hatch from the eggs and begin to feed on roots. Their feeding causes the roots to swell. The northern root-knot nematode completes its life cycle in one to two months. There are at least two generations per year in Michigan.

Damage and symptoms: Northern root-knot nematode feeding produces small root swellings called galls. Nematode-infested plants do not compete well for water and soil nutrients. These plants often appear to be water stressed even though there is sufficient soil moisture.

Management options: Crop rotation is the most effective way to manage the northern root-knot worm. Usually a one-year rotation out of the host crop is necessary to reduce nematode populations. Soil fumigants effectively control northern root-knot nematodes and may be necessary when populations are high.

CHAPTER 8

Review Questions

Chapter 8: Nematode Management

Write the answers to the following questions and then check your answers with those in the back of the manual.

1. Nematodes are small roundworms.
   A. True
   B. False

2. Plant-parasitic nematodes usually cause crop damage by feeding on the plant's:
   A. Leaves
   B. Stems
   C. Flowers
   D. Roots

3. A young nematode is called a:
   A. Nymph
   B. Juvenile
   C. Larva
   D. None of the above

4. Nematodes can move across a field or from one field to another by:
   A. Dust storms
   B. Contaminated machinery
   C. Floodwater
   D. All of the above

5. What type of mouthparts does a nematode have?
   A. Chewing
   B. Sucking
   C. Piercing/sucking
   D. Rasping

6. List three types of management tactics used to control nematodes. Give an example of each type.

7. Nematicides are applied to plant leaves to control root-feeding nematodes.
   A. True
   B. False

8-11. Match the following characteristics with the appropriate nematode.

A. Soybean cyst nematode
B. Corn needle nematode
C. Root-lesion nematode
D. Northern root-knot nematode

8. ___ Cannot be detected by sampling in the crop's root zone during the summer.
9. ___ Feeding results in the production of root galls.
10. ___ Usually managed by practicing crop rotation and planting resistant varieties.
11. ___ Extremely difficult to control with crop rotation.

12. The eggs of a soybean cyst nematode can continue to hatch over a period of:
   A. 1 week
   B. 10 hours
   C. 8 years
   D. 12 days

13. Which of the following nematodes does NOT enter the root to feed?

    A. Soybean cyst nematode
    B. Corn needle nematode
    C. Sugar beet cyst nematode
    D. Root-lesion nematode

14. Using crop rotation to stop a nematode population from growing and moving to other areas of a field is an example of which type of management system?

    A. Chemical.
    B. Prevention.
    C. Containment.
    D. Biological.

15. What is a cyst?

APPENDIX A

ANSWERS TO REVIEW QUESTIONS

Chapter 1 Integrated Pest Management

(1) Integrated pest management is a planned pest control program that combines control strategies to keep the pest population below economically damaging levels and to avoid adverse effects to humans, wildlife, and the environment.

(2) Cultural control – examples: host-plant resistance, maintaining healthy plants, changing the timing of harvest or planting, cultivation, field management, water management.

Biological control—examples: pathogens, parasitoids, predators.

Chemical control—examples: insecticide, herbicide, fungicide.

(3) Economic threshold—the number of pests (pest density) that requires a control action to prevent the pest population from increasing and causing economic damage.

(4) B. (5) D. (6) C.

(7) Cultural controls work by (1) preventing the pest from colonizing the crop or commodity, (2) creat-ing adverse conditions that reduce survival of the pest, and (3) reducing the impact of injury by the pest.

(8) A. (9) C. (10) B. (11) A. (12) B.

(13) C. (14) B. (15) A. (16) A. (17) B. (18) B.

(19) Tolerance is the amount of acceptable pesticide residue permitted by the Environmental Protection Agency (EPA) on a harvested crop.

(20) D. (21) A. (22) B. (23) C. (24) B. (25) D. (26) C. (27) A.

Chapter 2. Minimizing Pesticide Impact

(1) A.

(2) A supplemental label is any information from the manufacturer about how to use the product. Examples: special local needs labels (24c), emergency exemption labels (section 18), and use information issued by the manufacturer.

(3) B. (4) C. (5) D. (6) A. (7) B. (8) D.

(9) B. (10)B.

(11) Any five of the following are correct: use integrated pest management, consider the geology of the area, carefully select pesticides that are not likely to leach, follow pesticide label directions,.calibrate your equipment, measure accurately, avoid back-siphoning, consider weather conditions at the time of application, mix on an impervious pad, properly dispose of all pesticide wastes, and store pesticides away from water sources.

(12) C. (13) B. (14) A. (15) B. (16) A. (17) B.

(18) B. (19) A.

(20) 1. A map of all areas where pesticide applications occur.

2. A list of pesticide-sensitive sites near an application area.

3. Pesticide label and mandated restrictions.

4. Information for persons in sensitive areas on the type of pesticide used, the method of application, and the applicator's plan to minimize pesticide drift.

Chapter 3 Application Equipment

(1) D.

(2) The method of a pesticide application is influenced by target pest, the site of application, the available application equipment, and the cost and efficiency of alternative control methods.

(3) A. (4) A. (5) D. (6) C. (7) B. (8) A.

(9) B. (10) B. (11) B. (12) C. (13) B. (14) A.

(15) A pressure regulator controls the pressure in the spray system and therefore the amount of spray material delivered by the nozzles.

(16) C. (17) A. (18) B. (19) B. (20) D.

(21) 1. Check the spray system for leaks and drips by filling the tank with water and pressurizing the system.

2. Check the nozzles and strainers, making sure they are all the same type and are clean.

3. Measure the distance between the nozzle tip and the target and adjust, if necessary.

(22) B. (23) C. (24) B.

(25) Global positioning systems and geographical information systems help map fields and increase the accuracy of pesticide applications.

Chapter 4 Calibration

(1) Calibration of various systems is important because each system is a unique combination of pumps, nozzles, and other equipment.

(2) A. (3) B. (4) C. (5) C. (6) B. (7) D.

(8) A. (9) C. (10) B. (11) A. (12) A.

(13) D. (14) D. (15) B. (16) C. (17) A. (18) C.

Chapter 5 Insect Management

(1) D. (2) A.

(3) Metamorphosis is defined as the change in shape or form of an animal. An insect is said to undergo metamorphosis when it changes from the larval to pupal to adult life stage.

(4) A. (5) A. (6) C. (7) B. (8) B. (9) C.

(10) B.

(11) It is important to understand an insect's life cycle for pest management because each life stage is managed differently on the basis of its food source and habitat.

(12) B. (13) D. (14) E. (15) A. (16) C. (17) B.

(18) E. (19) B. (20) C. (21) C. (22) D. (23) B.

(24) A. (25) C. (26) A. (27) C. (28) B. (29) C.

(30) A. (31) D. (32) B. (33) A. (34) B. (35) A.

Chapter 6 Weed Management

(1) A weed is a plant growing where it is not wanted.

(2) B. (3) B. (4) C. (5) D. (6) A. (7) B.

(8) A. (9) A.

(10) Advantages –spot treatment, treat after problem occurs, herbicide is less susceptible to environmental conditions after treatment.

Disadvantages—need to correctly identify the weed, timing of application is critical, should not be applied to wet foliage, weather may not permit a timely application.

(11) B. (12) A. (13) B. (14) A.

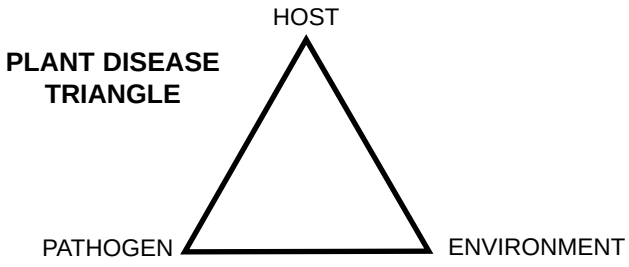
(15) A herbicide adjuvant is any substance that is added to a herbicide to enhance its effectiveness.

(16) B.

Chapter 7 Disease Management

(1) A. (2) C. (3) A. (4) C. (5) C.

(6)



(7) A.

(8) 1. Production of inoculum.

3. Spread of inoculum.

4. Infection.

5. Pathogen survival between susceptible crops.

(9) B. (10) C. (11) C. (12) D. (13) B. (14) B.

(15) C. (16) B. (17) A. (18) C. (19) D. (20) D.

(21) B. (22) A. (23) B. (24) C. (25) A. (26) B.

(27) C. (28) C. (29) A. (30) A. (31) A. (32) B.

(33) B.

(34) Any three of the following five are correct.

1. Plant high-yielding and resistant varies.
2. Plant more than one variety.
3. Treat all seeds before planting.
4. Scout fields to identify fields with potential problems.
5. Protect the flag leaf.

Chapter 8 Nematode Management

(1) A. (2) D. (3) B. (4) D. (5) C.

(6) Prevention tactics—example: crop rotation; using nematode-free seeds and transplants; planting nematode-resistant varieties; keeping farm equipment nematode free; maintaining good farm sanitation.

Containment tactics—keep nematode populations from moving to new fields or other areas of a field—example: practice prevention tactics such as crop rotation and planting nematode-free seeds and transplants to reduce nematode population.

Chemical control tactics—the application of nematicides—example: fumigant and non-fumigant nematicides applied to the soil.

(7) B. (8) B. (9) D. (10) A. (11) C. (12) C.

(13) B. (14) C.

(15) A cyst is the body of a dead adult female nematode of the genus Heterodera or Globodera, which may contain eggs.

APPENDIX B

CONVERSION TABLES

Area

144 square inches . . . . . .1 square foot
9 square feet . . . . . .1 square yard
43,560 square feet . . . . . .1 acre
4,840 square yards . . . . . .1 acre
160 square rods . . . . . .1 acre
640 acres . . . . . .1 square mile
2.5 acres . . . . . .1 hectare

Length

1 inch . . . . . 2.54 centimeters . . . . . .5.5 millimeters
1 foot . . . . . .12 inches
1 yard . . . . . .3 feet
1 rod . . . . . 5.5 yards . . . . . .16.5 feet
1 mile . . . . . 320 rods . . . . . 1,760 yards . . . . . .5,280 feet
1 meter . . . . . 39.4 inches . . . . . .1.09 yards
1 kilometer . . . . . 1,000 meters . . . . . .0.62 miles

Volume

1 tablespoon (tbsp or T) . . . . . .3 teaspoons (tsp or t)
1 fluid ounce . . . . . .2 tablespoons
8 fluid ounces . . . . . 16 tablespoons . . . . . .1 cup
16 fluid ounces . . . . . 2 cups . . . . . .1 pint
32 fluid ounces . . . . . 4 cups . . . . . .1 quart
128 fluid ounces . . . . . 4 quarts . . . . . .1 gallon
1 liter . . . . . 33.9 ounces . . . . . .1.06 quarts

Weight

1 ounce . . . . . .28.3 grams
1 pound . . . . . 16 ounces . . . . . .453.6 grams
2.2 pounds . . . . . 1 kilogram . . . . . .1,000 grams
1 ton . . . . . 2,000 pounds . . . . . .907 kilograms
1 metric ton . . . . . 1,000 kilograms . . . . . .2,205 pounds

APPENDIX C

GLOSSARY

ABDOMINAL PROLEGS—The false, peglike legs on the abdomen of a caterpillar.

ABSORPTION—The movement of a chemical into plants, animals (including humans), and/or microorganisms.

ACARICIDE—A pesticide used to control mites and ticks. A miticide is an acaricide.

ACTIVE INGREDIENT—The chemical or chemicals in a pesticide responsible for killing, poisoning, or repelling the pest. Listed separately in the ingredient statement on the pesticide label.

ACTION THRESHOLD—See ***economic threshold***

ACUTE TOXICITY—The capacity of a pesticide to cause injury within 24 hours following exposure. LD_{50} and LC_{50} are common indicators of the degree of acute toxicity. (See also ***chronic toxicity***.)

ADJUVANT—A substance added to a pesticide to improve its effectiveness or safety. Examples: penetrants, spreader-stickers, and wetting agents.

ADSORPTION—The binding of a chemical to a surface by physical or chemical attraction. Clay and high organic soils tend to adsorb pesticides.

AGGREGATION PHEROMONE—See ***pheromone***.

ALLELOPATHY—When one plant species releases toxic chemicals that eliminate a competing species.

ANAL PROLEGS—The false, peglike legs near the anus of a caterpillar.

ANNUAL—A plant that completes its life cycle in one year.

ANTI-SIPHONING DEVICE—A device attached to the filling hose that prevents backflow or back-siphoning from a spray tank into a water source.

ANTIDOTE—A treatment used to counteract the effects of pesticide poisoning or some other poison in the body.

ARACHNID—A wingless arthropod with two body regions and four pairs of jointed legs. Spiders, ticks, and mites are in the class Arachnida.

ARTHROPOD—An invertebrate animal characterized by a jointed body and limbs and usually a hard body covering that is molted at intervals. For example, insects, mites, and crayfish are in the phylum Arthropoda.

ATTRACTANT—A substance or device that will lure pests to a trap or poison bait.

AUGMENTATION—A periodic release of natural enemies to increase the present population; a method of biological control.

BACK-SIPHONING—The movement of liquid pesticide mixture back through the filling hose and into the water source.

BACTERIA (Bacterium)—Microscopic organisms, some of which are capable of producing diseases in plants and animals. Others are beneficial, killing pests.

BACTERICIDE—Chemical used to control bacteria.

BAIT—A food or other substance used to attract a pest to a pesticide or to a trap.

BAND APPLICATION—The application of a pesticide in a strip or band of a certain width.

BENEFICIAL INSECT—An insect that is useful or helpful to humans; usually insect parasites, predators, pollinators, etc.

BIENNIAL—A plant that requires two growing seasons to complete its life cycle.

BIOLOGICAL CONTROL—Control of pests using predators, parasitoids, and disease-causing organisms. May be naturally occurring or introduced.

BOTANICAL PESTICIDE—A pesticide produced from chemicals found in plants. An example is pyrethrum.

BRAND NAME—The name or designation of a specific pesticide product or device made by a manufacturer or formulator; a marketing or trade name.

BROADCAST APPLICATION—A uniform pesticide application to a field or site.

CALIBRATE, CALIBRATION OF EQUIPMENT—The measurement of dispersal or output and adjustments made to control the rate of dispersal of pesticides.

CARBAMATES (N-methyl carbamates)—A group of pesticides containing nitrogen and used as insecticides, fungicides, and herbicides. The N-methyl carbamates are insecticides and inhibit ***cholinesterase*** in animals.

CARCINOGENIC—The ability of a chemical to induce malignant tumors (cancer).

CARRIER—An inert liquid, solid, or gas added to an active ingredient to make a pesticide dispense effectively. A carrier is also the material, usually water or oil, used to dilute the formulated product for application.

CARRYOVER (HERBICIDE)—When a herbicide is not broken down during the season of application and persists in quantities large enough to injure succeeding crops.

CERTIFIED APPLICATORS—Individuals who are certified to use or supervise the use of any restricted-use pesticide covered by their certification.

CHEMICAL NAME—The scientific name of the active ingredient(s) found in the formulated product. This complex name is derived from the chemical structure of the active ingredient.

CHEMICAL CONTROL—Pesticide application to kill pests.

CHEMTREC—The Chemical Transportation Emergency Center has a toll-free number (800-424-9300) that provides 24-hour information for chemical emergencies such as spills, leaks, fires, or accidents.

CHOLINESTERASE, ACETYLCHOLINESTERASE—An enzyme in animals that helps regulate nerve impulses. This enzyme is inhibited by N-methyl carbamate and organophosphate pesticides.

CHRONIC TOXICITY—The ability of a material to cause injury or illness (beyond 24 hours following exposure) from repeated, prolonged exposure to small amounts of pesticide. (See also ***acute toxicity***.)

COMMERCIAL APPLICATOR—A person applying restricted-use or general-use pesticides as a scheduled or required work assignment, holding out for hire, or advertising the business of applying pesticides.

COMMON NAME—A name given to a pesticide's active ingredient by a recognized committee on pesticide nomenclature. Many pesticides are known by a number of trade or brand names, but each active ingredient has only one recognized common name.

CONCENTRATION—Refers to the amount of active ingredient in a given volume or weight of formulated product.

CONTACT PESTICIDE—A compound that causes death or injury to insects when it touches them. It does not have to be ingested. Often used in reference to a spray applied directly on a pest.

CONTAMINATION—The presence of an unwanted substance (sometimes pesticides) in or on plants, animals, soil, water, air, or structures.

COTYLEDONS—The first leaf or pair of leaves of a seedling.

CROSS-RESISTANCE—When a pest resistant to one type of pesticide is also resistant to other pesticides with a similar mode of action.

CULTURAL CONTROL—A pest control method that includes changing agricultural production practices, such as sanitation, work practices, tillage, crop rotation, etc.

CURATIVE—The application of a control tactic after the pest has arrived.

CYST (NEMATODES)—The body of a dead adult female nematode of the genus *Heterodera* or *Globodera*, which may contain eggs.

DAMPING-OFF—The destruction of seedlings near the soil line, resulting in the seedlings falling to the ground.

DECONTAMINATE—To remove or break down a pesticide from a surface or substance.

DEGRADATION—The process by which a chemical compound or pesticide is reduced to simpler compounds by the action of microorganisms, water, air, sunlight, or other agents. Degradation products are usually but not always less toxic than the original compound.

DEPOSIT—The amount of pesticide on treated surfaces after application.

DERMAL TOXICITY—The ability of a pesticide to cause acute illness or injury to a human or animal when absorbed through the skin. (See ***exposure route***.)

DETOXIFY—To render a pesticide's active ingredient or other poisonous chemical less toxic.

DIAGNOSIS—The positive identification of a problem and its cause.

DILUENT—Any liquid, gas, or solid material used to dilute or weaken a concentrated pesticide.

DISEASE—A disturbance of normal plant function; caused by bacteria, fungi, virus, or environmental conditions.

DISEASE CYCLE—The basic chain of events involved in disease development.

DISINFECTANT—A chemical or other agent that kills or inactivates disease-producing microorganisms.

DOSE, DOSAGE—Quantity, amount, or rate of pesticide applied to a given area or target.

DRIFT—The airborne movement of a pesticide spray or dust beyond the intended target area.

DRIFT MANAGEMENT PLAN—A written plan required of commercial and private applicators by Michigan Regulation 637 whenever there is a chance of a spray application drifting from the target onto non-target and off-site sensitive areas.

DUST—A finely ground, dry pesticide formulation containing a small amount of active ingredient and a large amount of inert carrier or diluent such as clay or talc.

ECONOMIC DAMAGE—The amount of injury that will justify the cost of applied control measures.

ECONOMIC THRESHOLD (ET, ACTION THRESHOLD)—The pest density at which action must be taken to prevent the pest population from causing economic damage.

ECOSYSTEM—The pest management unit. It includes a community (of ***populations***) with the necessary physical and biotic (food, hosts) supporting factors that allow an infestation of pests to persist.

EMULSIFIABLE CONCENTRATE—A pesticide formulation produced by mixing or suspending the active ingredient (the concentrate) and an emulsifying agent in a suitable carrier. When it's added to water, a milky emulsion is formed.

EMULSIFYING AGENT (EMULSIFIER)—A chemical that aids in the suspension of one liquid in another that normally would not mix together.

EMULSION—A mixture of two liquids that are not soluble in each other. One is suspended as very small droplets in the other with the aid of an emulsifying agent.

ENCAPSULATED FORMULATION—A pesticide formulation with the active ingredient enclosed in capsules of polyvinyl or other materials; principally used for slow release.

ENDANGERED SPECIES—A plant or animal species whose population is reduced to the extent that a federal agency has designated it as being in danger of becoming extinct.

ENVIRONMENT—All of our physical, chemical, and biological surroundings, such as climate, soil, water, and air, and all species of plants, animals, and microorganisms.

ENVIRONMENTAL PROTECTION AGENCY OR EPA—The federal agency responsible for ensuring the protection of humans and the environment from potentially adverse effects of pesticides.

EPA ESTABLISHMENT NUMBER—A number assigned to each pesticide production plant by the EPA. The number indicates the plant at which the pesticide product was produced and must appear on all labels of that product.

EPA REGISTRATION NUMBER—An identification number assigned to a pesticide product when the product is registered by the EPA. The number must appear on the label for the product.

ERADICATION—The complete elimination of a (pest) population from a designated area.

EXOSKELETON—The external hardened covering or skeleton of an insect; periodically shed.

EXPOSURE ROUTE OR COMMON EXPOSURE ROUTE—The manner (dermal, oral, or inhalation / respiratory) by which a pesticide may enter an organism.

FIFRA—The Federal Insecticide, Fungicide, and Rodenticide Act; a federal law and its amendments that regulate pesticide registration and use.

FLOWABLE—A pesticide formulation in which a very finely ground solid particle is suspended (not dissolved) in a liquid carrier.

FOOD TOLERANCE—The host's ability to withstand pest injury.

FORMULATION—The pesticide product as purchased, containing a mixture of one or more active ingredients, carriers (inert ingredients), and other additives making it easy to store, dilute, and apply.

FRUITING BODY—The part of a fungus that contains spores.

FUMIGANT—A pesticide formulation that volatilizes, forming a toxic vapor or gas that kills in the gaseous state. It usually penetrates voids to kill pests.

FUNGICIDE—A chemical used to control fungi.

FUNGUS (plural: fungi)—A group of small, often microscopic organisms in the plant kingdom that cause rot, mold, and disease. Fungi need moisture or a damp environment (wood rots require at least 19 percent moisture).

GENERAL-USE PESTICIDE—A pesticide that can be purchased and used by the general public. (See also restricted-use pesticide.)

GEOGRAPHIC INFORMATION SYSTEM (GIS)—An organized collection of computer hardware, software, geographic data, and personnel designed to capture, manipulate, analyze, and display geographically referenced data.

GLOBAL POSITIONING SYSTEM (GPS)—A portable, satellite-based system that will establish the real-world location (position) of the GPS receiver.

GRANULE—A dry pesticide formulation. The active ingredient is either mixed with or coated onto an inert carrier to form a small, ready-to-use, low-concentrate particle that normally does not present a drift hazard. Pellets differ from granules only in their precise uniformity, larger size, and shape.

GROUNDWATER—Water sources located beneath the soil surface from which spring water, well water, etc., are obtained. (See also ***surface water***.)

HAZARD—See ***risk***.

HERBICIDE—A pesticide used to kill plants or inhibit plant growth.

HOPPERBURN—A V-shaped yellow marking resulting from feeding of potato leafhopper.

HOST—Any animal or plant on or in which another lives for nourishment, development, or protection.

HOST RESISTANCE—The defense mechanism of an animal or plant against a pest; sometimes host-plant resistance. (See ***resistance***.)

HYPHA (plural: hyphae)—A single, delicate, threadlike structure of fungus.

IGR, INSECT GROWTH REGULATOR—A pesticide that mimics insect hormones that control molting and the development of some insect systems affecting the change from immature to adult. (See ***juvenile hormone***.)

INCUBATION PERIOD—The time between first exposure to a pathogen and first appearance of symptoms.

INERT INGREDIENT—In a pesticide formulation, an inactive material without pesticidal activity.

INFECTION—The establishment of a pathogen with a host.

INFECTIOUS DISEASE—Disease caused by pathogens such as bacteria, viruses, and fungi; can be spread from plant to plant.

INGREDIENT STATEMENT—The portion of the label on a pesticide container that gives the name and amount of each active ingredient and the total amount of inert ingredients in the formulation.

INHALATION—Taking a substance in through the lungs; breathing in. (See ***exposure route***.)

INOCULUM—A pathogen source that can infect and cause disease.

INSECT GROWTH REGULATOR—See ***IGR***.

INSECTICIDE—A pesticide used to manage or prevent damage caused by insects.

INSECTS, INSECTA—A class in the phylum Arthropoda characterized by a body composed of three segments (head, thorax, and abdomen) and three pairs of legs.

INTEGRATED PEST MANAGEMENT——See ***IPM***.

IPM—Integrated pest management. A planned pest control program in which various methods are integrated and used to keep pests from causing economic, health-related, or aesthetic injury. IPM emphasizes reducing pests to a tolerable level. Pesticide application is not the primary control method but is an element of IPM, as are cultural, mechanical, and biological methods. IPM programs emphasize communication, monitoring, inspection, and evaluation (keeping and using records).

JUVENILE—The immature or larval stages of nematodes; commonly referred to as J1, J2, J3, and J4.

JUVENILE HORMONE—A hormone produced by an insect that inhibits change or molting. As long as juvenile hormone is present, the insect remains immature and does not develop into an adult.

LABEL—All printed material attached to or on a pesticide container.

LABELING—The pesticide product label and other accompanying materials that contain directions that pesticide users are legally required to follow.

LARVA (plural: larvae)—An early developmental stage of insects with complete metamorphosis. Insects hatch out of the egg as larvae before becoming pupae (resting stage) and then adults.

LC_{50}—Lethal concentration. The concentration of a pesticide, usually in air or water, that kills 50 percent of a test population of animals. LC_{50} is usually expressed in parts per million (ppm). The lower the LC_{50} value, the more acutely toxic the chemical.

LD_{50}—Lethal dose. The dose or amount of a pesticide that can kill 50 percent of the test animals when eaten or absorbed through the skin. LD_{50} is expressed in milligrams of chemical per kilogram of body weight of the test animal (mg / kg). The lower the LD_{50}, the more acutely toxic the pesticide.

LEACHING—The movement of a substance on water downward through soil.

MESOTHORAX—The second segment of an insect's t***horax***. One pair of legs and usually one pair of wings are attached.

METAMORPHOSIS—A change in the shape, or form, of an animal. Usually refers to insect development.

METATHORAX—The third segment of an insect's ***thorax***. One pair of legs and often one pair of wings are attached.

MICROBIAL DEGRADATION—Breakdown of a chemical by microorganisms.

MICROBIAL PESTICIDE—Bacteria, viruses, fungi, and other microorganisms used to control pests. Also called biorationals.

MICROORGANISM—An organism so small it can be seen only with the aid of a microscope.

MITICIDE—A pesticide used to control mites.

MODE OF ACTION—The way in which a pesticide exerts a toxic effect on the target plant or animal.

MOLLUSCICIDE—A chemical used to control snails and slugs.

MOLT—Periodic shedding of the outer layer of the insect skeleton.

MONITORING—On-going surveillance. Monitoring includes inspection and record keeping. Monitoring records allows technicians to evaluate pest population suppression, identify infested or non-infested sites, and manage the progress of the management or control program.

MYCELIUM—A mass of fungal hyphae; has a fuzzy appearance.

NECROSIS—Death of plant or animal tissues that results in the formation of discolored, sunken, or dead (necrotic) areas.

NEMATODE—A small, slender, colorless roundworm; nematodes live in soil and water or as parasites.

NEMATICIDE—A chemical used to control nematodes.

NON-INFECTIOUS DISEASE—Disease caused by nonliving agents such as drought, soil compaction, temperature or moisture extremes, nutrient deficiency, etc.; can not reproduce and spread.

NON-POINT SOURCE POLLUTION—Pollution from a generalized area or weather event.

NON-TARGET ORGANISM—Any plant or animal other than the intended target(s) of a pesticide application.

NOZZLE FLOW RATE—The amount of material that passes through the nozzle in a specific amount of time; depends on pressure and tip size.

NYMPH—The immature stage of insects with gradual metamorphosis. Nymphs become adults.

ORAL TOXICITY—The ability of a pesticide to cause injury or acute illness when taken by mouth. One of the common exposure routes.

ORGANOPHOSPHATES—A large group of pesticides that contain the element phosphorus and inhibit ***cholinesterase*** in animals.

PARASITOID—An organism that lives during its development in or on the body of a single host organism, eventually killing it.

PATHOGEN—A disease-causing organism.

PERENNIAL—A plant that lives for more than two years.

PERSONAL PROTECTIVE EQUIPMENT (PPE)—Devices and clothing intended to protect a person from exposure to pesticides. Includes such items as long-sleeved shirts, long trousers, coveralls, suitable hats, gloves, shoes, respirators, and other safety items as needed.

PEST—An undesirable organism (plant, animal, bacterium, etc.); any organism that competes with people for food, feed, or fiber, causes structural damage, is a public health concern, reduces aesthetic qualities, or impedes industrial or recreational activities.

PESTICIDE—A chemical or other agent used to kill, repel, or otherwise control pests or to protect from a pest.

PETIOLE—The stalk of a leaf.

pH—A measure of the acidity / alkalinity of a liquid; pH7 is neutral, below pH7 is acid, and above pH7 (up to 14) is basic or alkaline.

PHEROMONE—A substance emitted by an animal to influence the behavior of other animals of the same species. Examples are sex pheromones (to attract mates) and aggregation pheromones (to keep members of the same species together in a group). Some pheromones are synthetically produced for use in insect traps.

PHOTODEGRADATION—Breakdown of chemicals by the action of light.

PHYTOTOXICITY—Injury to plants caused by a chemical or other agent.

POINT OF RUNOFF—The point at which a spray starts to run or drip from the surface to which it is applied.

POINT SOURCE POLLUTION—Pollution from a specific source.

POISON CONTROL CENTER—A local agency, generally a hospital, that has current information on the proper first aid techniques and antidotes for poisoning emergencies. Centers are listed in telephone directories.

POPULATION—Individuals of the same species. The populations in an area make up a community. (See ***ecosystem***.)

POSTEMERGENT HERBICIDE—Herbicide applied after weeds have emerged to kill them by contacting the foliage.

PREEMERGENT HERBICIDE—Herbicide applied before emergence of weeds to kill them as they develop (sprout).

PREHARVEST INTERVAL—The minimum amount of time in days between the last application and harvest. The preharvest interval can be found on the pesticide label.

PRECIPITATE—A solid substance that forms in a liquid and settles to the bottom of a container; a material that no longer remains in suspension.

PREDATOR—An animal that attacks, kills, and feeds on other animals. Examples of predaceous animals are hawks, owls, snakes, and many insects.

PRONOTUM—The area just behind an insect's head (i.e., the upper plate of the ***prothorax***).

PROTECTANT—A chemical applied to a plant or animal to prevent a pest problem.

PROTHORAX—The first segment of an insect's ***thorax***. One pair of legs is attached.

PUPA (plural: pupae)—The developmental (resting) stage of insects with complete metamorphosis, when major changes from the larval to the adult form occur.

RATE OF APPLICATION—The amount of pesticide applied to a plant, animal, unit area, or surface; usually measured as per acre, per 1,000 square feet, per linear foot, or per cubic foot.

REENTRY INTERVAL (REI)—The length of time following an application of a pesticide when entry into the treated area is restricted.

REGISTERED PESTICIDES—Pesticide products that have been registered by the Environmental Protection Agency for the uses listed on the label.

REPELLENT—A compound that keeps insects, rodents, birds, or other pests away from humans, plants, domestic animals, buildings, or other treated areas.

RESIDUAL PESTICIDE—A pesticide that continues to remain effective on a treated surface or area for an extended period following application.

RESIDUE—The pesticide active ingredient or its breakdown product(s) that remain in or on the target after treatment.

RESISTANCE—The inherited ability of a pest to tolerate the toxic effects of a particular pesticide.

RESTRICTED-USE PESTICIDE—A pesticide that can be purchased and used only by certified applicators or persons under their direct supervision. A pesticide classified for restricted use under FIFRA, Section 3(d)(1)(C).

RHIZOME—An underground stem capable of sending out roots and leafy shoots.

RISK—A probability that a given pesticide will have an adverse effect on humans or the environment in a given situation.

RODENTICIDE—A pesticide used to control rodents.

RUNOFF—The movement of water and associated materials on the soil surface. Runoff usually proceeds to bodies of surface water.

SANITATION—The removal of infected plant parts, decontamination of tools, equipment, hands, etc.

SCLEROTIA—A mass of hyphae and food that allows the fungus to survive long periods of extreme hot or cold temperatures and lack of water.

SCOUTING—Regular monitoring of a crop or site to determine possible pest problems.

SCUTUM—Shieldlike structure located near the front part of the ***mesothorax*** of an insect.

SIGNAL WORDS—Required word(s) that appear on every pesticide label to denote the relative toxicity of the product. Signal words are DANGER-POISON, DANGER, WARNING, and CAUTION.

SITE—Areas of pest infestation. Each site should be treated specifically or individually.

SOIL DRENCH—To soak or wet the ground surface with a pesticide. Large volumes of the pesticide mixture are usually needed to saturate the soil to any depth.

SOIL FUMIGANT—A toxic gas or volatile substance that is used to kill soil microorganisms.

SOIL INJECTION—The placement of a pesticide below the surface of the soil; common application method for nematicides.

SOIL INCORPORATION—The mechanical mixing of a pesticide product with soil.

SOLUTION—A mixture of one or more substances in another substance (usually a liquid) in which all the ingredients are completely dissolved. Example: sugar in water.

SOLVENT—A liquid that will dissolve another substance (solid, liquid, or gas) to form a solution.

SPECIES—See ***taxonomy***.

SPORE—The reproductive stage of fungi.

SPRAY DRIFT—Movement of airborne spray from the intended area of application.

STOMACH POISON—A pesticide that must be eaten by a pest to be effective; it will not kill on contact.

STOLONS—An aboveground creeping stem that can root and develop new shoots.

STYLET—A long, slender, hollow feeding structure of nematodes and some insects.

SUPPLEMENTAL LABELING—Pesticide label information that appears on a separate piece of paper and contains information on the site, pest, rate, etc. Supplemental labeling may be supplied at the time of purchase or requested from the dealer.

SURFACE WATER—Water on the earth's surface: rivers, lakes, ponds, streams, etc. (See also ***groundwater***.)

SUSPENSION—Pesticide mixtures consisting of fine particles dispersed or floating in a liquid, usually water or oil. Example: wettable powders in water.

TARGET—The plants, animals, structures, areas, or pests at which the pesticide or other control method is directed.

TAXONOMY—The classification of living organisms into groups: kingdom, phylum, class, order, family, genus, and species.

TECHNICAL MATERIAL—The pesticide active ingredient in pure form as it is manufactured by a chemical company. It is combined with inert ingredients or additives in formulations such as wettable powders, dusts, emulsifiable concentrates, or granules.

THORAX—The middle part of an insect's body between the head and the abdomen. It is divided into three segments—***prothorax***, ***mesothorax***, and ***metathorax***. A pair of legs is attached to each thoracic region.

THRESHOLD—A level of pest density at which the pest or its damage becomes unacceptable and control measures are required.

TOXIC—Poisonous to living organisms.

TOXICANT—A poisonous substance such as the active ingredient in a pesticide formulation.

TOXICITY—The ability of a pesticide to cause harmful, acute, delayed, or allergic effects. The degree or extent to which a chemical or substance is poisonous.

TOXIN—A naturally occurring poison produced by plants, animals, or microorganisms. Examples: toxic saliva of potato leafhoppers, vomitoxin produced by the fungus *Fusarium graminearum*.

USE—The performance of pesticide-related activities requiring certification include: application, mixing, loading, transport, storage, or handling after the manufacturing seal is broken; care and maintenance of application and handling equipment; and disposal of pesticides and their containers in accordance with label requirements. Uses not needing certification are long-distance transport, long-term storage, and ultimate disposal.

VAPOR PRESSURE—The property that causes a chemical to evaporate. The higher the vapor pressure, the more volatile the chemical (the easier it will evaporate).

VECTOR—A carrier; an animal (e.g., insect, nematode, mite) that can carry and transmit a pathogen from one host to another.

VERTEBRATE—Animal characterized by a segmented backbone or spinal column.

VIRUS—Ultramicroscopic parasites composed of proteins. Viruses can multiply only in living tissues and cause many animal and plant diseases.

VOLATILITY—The degree to which a substance changes from a liquid or solid state to a gas at ordinary temperatures when exposed to air.

VOMITOXIN—A toxin produced by the fungus Fusarium graminearum (wheat scab) that contaminates wheat; toxic to mammals.

WATER TABLE—The upper level of the water-saturated zone in the ground.

WETTABLE POWDER—A dry pesticide formulation in powder form that forms a suspension when added to water.

STUDY GUIDE FOR
AGRICULTURAL PLANT DISEASES

The educational material in this study guide is practical information to prepare you to meet the written test requirements. It doesn't include all the things you need to know about this pest-control subject or your pest-control profession. It will, however, help you prepare for your test.

Contributors include the Utah Department of Agriculture and Utah State University Extension Service. This study guide is based on a similar one published by the Colorado Department of Agriculture. Materials for that guide were prepared by Colorado State University Extension Service. Other contributors include: University Cooperative Extension Service personnel of California, Kansas, New York, Oregon, Pacific Northwest, Pennsylvania, and Wyoming. Other contributors were the U.S. Department of Agriculture -- Forest Service, the United States
Environmental Protection Agency (Region VIII), the Department of Interior -- Bureau of Reclamation, and Metro Pest Management.

The information and recommendations contained in this study guide are based on data believed to be correct. However, no endorsement, guarantee or warranty of any kind, expressed or implied, is made with respect to the information contained herein.

Other topics that may be covered in your examinations include First Aid, Personal Protective Equipment (PPE), Protecting the Environment, Pesticide Movement, Groundwater, Endangered Species, Application Methods and Equipment, Equipment Calibration, Insecticide Use, Application, Area Measurements, and Weights and Measures. Information on these topics can be found in the following books:

1. **National Pesticide Applicator Certification Core Manual,** Published by the National Association of State Departments of Agriculture Research Foundation.

2. **The Workers Protection Standard for Agricultural Pesticides – How to Comply: What Employers Need to Know.** U.S. EPA, Revised September 2005, Publication EPA/735-B-05-002.

These books can be obtained from the Utah Department of Agriculture or Utah State University Extension Service. Please contact your local Utah Department of Agriculture Compliance Specialist or Utah State University extension agent.

The following individuals at Utah State University contributed to the revision of this manual: F.R. Beard, H.M. Deer, S. Thomson, J.B Karren, D.G. Alston, A.H. Roe, and S.A. Dewey.

INSECT PEST MANAGEMENT

A critical component of agricultural production is the management of insect pest organisms (arthropods). The insects and insect relatives that compete with humans for food and fiber, or attack us directly, are pests. Many of the insect pest problems involving agricultural crops originated with and/or have been aggravated by traditional farming practices. Crop production involves the concentration of host plants and creates an ideal situation for insect development and growth. These enhanced growing conditions lead to a wide range of complex problems without simple solutions.

Insects thrive in more environments than any other group of animals. They live on the earth's surface, within the soil, and in water. Insects populate deserts, rain forests, hot-springs, snowfields, and caves. They compete very successfully with humans for the choicest plants and cause damage to plants in the following ways.

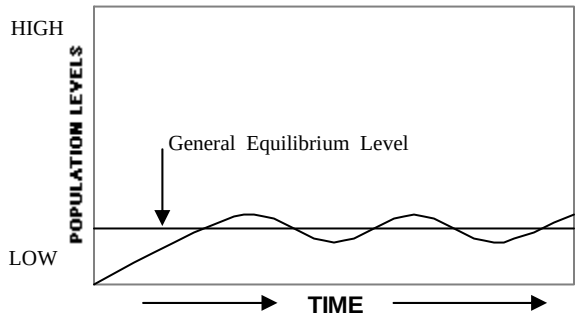
- Feed on leaves,
- Feed on and into fruit, seeds, and nuts
- Feed on and tunnel into roots,
- Tunnel or bore into stems, stalks, branches, and trunks,
- Suck the sap from leaves, stems, roots, fruits, and flowers, and
- Transmit plant disease agents.

The majority of insects are not pests. Many assist humans by pollinating plants and feeding on other insects that are pests. However, most agricultural plants are damaged, weakened, or killed by insect pests. This results in reduced yields, lowered quality, and damaged plants or plant products that cannot be sold. Even after harvest, insects continue their damage in stored or processed products. Insects also feed on and in animals, including humans. Some of these pests carry disease agents that have caused millions of deaths to livestock and humans.

Insect management requires the recognition and understanding of target-insect habits, life cycles, and control measures. The first step in controlling insect pests is to properly identify the pest and recognize the problems caused.

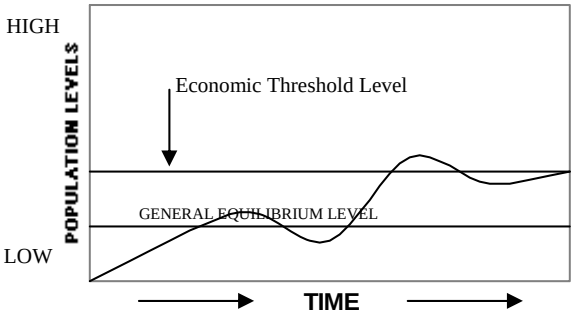
ECONOMICS OF INSECT MANAGEMENT

The use of pesticides to control insect pests is a necessary part of large-scale crop production and the decision to treat agricultural crops with an insecticide should be based on economics. To assist with this decision, two phrases related to infestation level are utilized, economic threshold level and economic injury level.



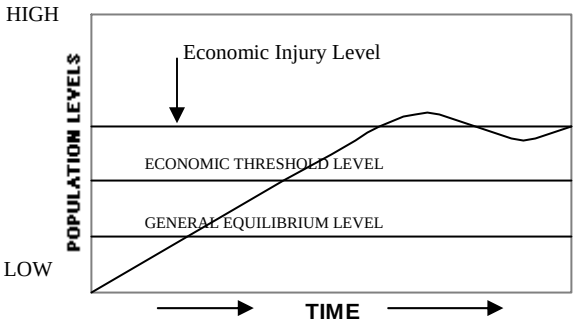
Economic threshold level is the insect population density at which control measures are necessary to prevent an increasing pest population from reaching the economic injury level.

Economic injury level is defined as the lowest population density that will cause economic crop damage. Insect populations normally fluctuate above and below a **general equilibrium level** that represents the average population size. Profits may be slightly affected when pest populations are present at this level.



When pest populations increase to damaging numbers at the **economic threshold level**, control measures must be initiated or increased crop losses occur. At the **economic threshold level**, damage to the crop may justify the cost of control measures. If control measures are not taken and the pest population continues to increase, the quantity and quality of the crop will be substantially reduced. This point is referred to as the **economic injury level**. This level may vary from crop to crop, area to

area, season to season, and/or with the market price of the crop.



It is common practice for preventive treatments to be employed on a calendar basis. Treatment also occurs when insects are initially seen, the **visibility threshold**. Application decisions based on these conditions are justified if there are scheduling problems with equipment or labor, the size of the application area is large, or past experience dictates such practices.

Insecticide applications are best conducted when the pest or evidence of the pest is present in sufficient numbers to reach the **economic threshold level**. When insect infestation reaches the **economic injury level**, the treatment is necessary to prevent substantial loss of the crop.

INSECT CHARACTERISTICS

Knowledge of insect classification, growth and development, and life cycles is necessary for conducting management programs. Proper insect identification is perhaps the most essential step in insect pest management. Life cycle data is also important for scheduling control measures. With proper identification and an understanding of an insect's life cycle, control measures can be applied when the pest is in its most vulnerable stage of development.

The two things that all adult insects have in common are six jointed legs and three body regions. For identification purposes, the important parts to look at are the wings and mouth parts. Some insects have no wings, while others have two or four. The wings vary in shape, size, thickness and structure. Insects with chewing mouth parts have toothed jaws that bite and tear the food. Insects with piercing-sucking mouth parts have a long beak that they force into a plant or animal to suck out fluids or blood.

Almost all insects change in shape, form, and size during their lives. This change is called metamorphosis. Some primitive insects change only in size as they develop. A nymph that looks like a tiny adult hatches from the egg and goes through several stages. These nymphs change into wingless adults. The adult lays eggs. Other insects change form slightly. Their nymphs hatch from eggs. The nymphs, having no wings, go through several growing stages and finally change into winged adults.

Other insects change completely. They go through four life stages. Beginning as an egg (stage 1), the larva hatches (stage 2) as a worm, caterpillar, grub or maggot. This is the stage in which insects grow the most and do the most damage. When full grown, the larva changes into a pupa (stage 3). From the pupa stage, it changes into the adult (stage 4). The adult stage usually has wings.

INSECT OUTBREAKS

Insect epidemics or outbreaks are usually caused by:

1. Large-scale culture of a single crop,
2. Introduction of an insect pest into a favorable new area that lacks natural enemies,
3. Favorable weather conditions for rapid development and multiplication of an insect, such conditions may be unfavorable to natural enemies,
4. Use of insecticides that kill the natural enemies of a pest, create other favorable conditions for a pest, reduce competing species of pests, and/or allow it to multiply unmolested or only partially controlled,
5. Use of poor cultural practices that encourage buildup of pest infestations, and
6. Destruction of natural biotic communities that otherwise provide regulation of insect population levels.

INSECT CONTROL TECHNIQUES

Preventive control measures are employed when past experience has shown an insect to be an annual problem. Early-season insecticide treatment tends to control certain pest species more effectively. Preventive treatments allow the application of insecticide before the crop foliage is hard to penetrate with sprays, granules, or dusts. Preventive control measures also reduce pest populations before the insects can advance through their stages of development and begin reproduction.

Preventive control occurs prior to the **economic injury level**. Such measures are undertaken with the belief that an insecticide will have to be applied and early application is less expensive and/or more effective than a later application.

Biological control can be defined as the action of parasites, predators or pathogens (disease producing organisms) on an unwanted host or prey population.

These agents produce a lower population level than would prevail in their absence. Generally, biological control refers to manipulations by humans, as distinguished from natural enemies and natural control.

Biological control may offer a number of distinct advantages, including permanence, safety, and economy. Once biological control is established, it can be relatively permanent with no side effects such as toxicity, environmental pollution, or use hazards. There are three traditional biological control methods:

1. Introduction of exotic species of parasites, predators, or pathogens,
2. Conservation of parasites or predators, and
3. Increase of parasites or predators.

Natural enemies can assist in controlling the insect pests found in most crop ecosystems, but biological controls are not suitable for many pest situations. It takes time for the parasites and/or predators to bring the pest under control. Normally, a grower who is constrained by markets or economic injury level infestations cannot wait for biological controls to work.

Other technical difficulties involve the determination of which parasites or predators to introduce, whether to use more than one parasitic species at a time, how to eliminate secondary parasites that prey on the beneficial form, and whether a program of continuous releases may be feasible. Also, there is the problem of protecting such predators and/or parasites from insecticides.

Mechanical control is the reduction of insect populations by means of devices that affect them directly or alter their physical environment radically. These methods are often hard to distinguish from cultural methods. However, mechanical controls involve special physical measures rather than normal agricultural practices. They tend to require considerable time and labor and often are impractical on a large scale.

Hand picking and trapping are familiar mechanical methods of insect control. Screens, barriers, sticky bands, and shading devices are also mechanical methods or devices. Hopper-dozers and drags are stypes of specialized control equipment for collecting or smashing insects.

Legal control is the lawful regulation of areas to eradicate, prevent, or control infestation in order to reduce the damage by insects. This mainly involves the use of quarantines and pest control procedures. Federal and state officials often work with legally established local, community, or county districts, as in grasshopper control projects.

Cultural control is the reduction of insect populations by using agricultural practices. It has also been defined as "making environments unfavorable for pests." These methods, more or less associated with agricultural production, usually involve certain changes in normal farming practices rather than the addition of special procedures.

Scheduling cultural practices to occur during the most vulnerable time of an insect's life cycle is a very effective control measure. The insect's favorable environment is altered to kill the pests or reduce their reproduction. Since cultural methods are usually economical, they are useful against field crop insects.

Types of cultural control practices are:

1. **Rotation**: Certain kinds of crop rotations may help control pests. Insects that are reduced effectively by rotations usually have a long life cycle and a limited host range and are relatively immobile in some stage of their development. Changing crops in a rotation system isolates such pests from their food supply. Wireworms, white grubs, and corn rootworms are good examples.
2. **Location**: Careful choice of crops to be planted adjacent to each other may help reduce insect damage.
3. **Trap crop**: Small plantings of a susceptible or preferred crop may be established near a major crop to act as a "trap." When the insects have been attracted to the trap crop, they are treated with insecticides, plowed under, or both.
4. **Tillage**: The use of tillage operations to reduce populations of soil-inhabiting insects may work in several ways. Tillage can change the physical conditions of the soil; bury, expose, or mechanically damage the insect at a particular stage of life; eliminate insect host plants; and hasten growth or increase vigor of the crop.
5. **Sanitation:** Removing crop residues, disposing of volunteer plants, and burning chaff stacks are measures commonly applied against vegetable and field crop insects.
6. **Timing**: Changes in planting time or harvesting time are used to keep the infesting stage of an insect separated from the susceptible stage of the host.
7. **Resistant varieties**: The sources of resistance to insects in crops have been classified as nonpreference, antibiosis, and tolerance. Insect **nonpreference** for a certain host plant is related to color, light reflection, physical structure of the surface, and chemical stimuli such as taste and odor. **Antibiosis** is the adverse effect of the plant on the insect. This may be caused either by the harmful effect of a specific chemical or by the lack of a specific nutrient requirement. **Tolerance** is the term applied to the general vigor of certain plants that may be able to withstand the attack of pests such as

sucking insects. Tolerance also includes the ability of the plant to repair tissues and recover from an attack.

Advantages of the use of resistant varieties include a cumulative and persistent effect which often eliminates insect damage within a few seasons, lack of dangers to humans and domestic animals, low cost (once the program is established), and usefulness in integrated control systems.

Reproductive control is the reduction of insect populations by means of physical treatments or substances that cause sterility, alter sexual behavior, or otherwise disrupt the normal reproduction of insects.

Chemical control is the reduction of insect populations or prevention of insect injury by the use of insecticides to poison them, attract them to other devices, or repel them from specified areas.

In most cases, despite adverse publicity, insecticides are the most effective method of managing insects. Insecticides are highly efficient and economical, and they can be applied quickly and have an immediate impact on insect populations. When insect populations approach economic threshold levels in market crops, and natural controls are inadequate, insecticide applications are the only option.
Insecticides are essential for:

1. Maintaining adequate crop protection,
2. Protecting forest resources, and
3. Preserving the health and well being of humans.

An advantage of using insecticides in many crop ecosystems is that more than one major insect can be controlled with a single application. Chemical insecticides are especially important as fast-acting insect management tools. Insecticides should be used in a manner that is harmonious with other elements of the agricultural ecosystem so that they amplify other control agents. Insecticides have the following limitations:

1. Insecticides contribute to the development of insects resistant to chemical control,
2. Insecticides temporarily control insect populations, but often require repeated treatments,
3. Insecticide residues are restricted when present in harvested crops,
4. Insecticides unleash secondary pests resulting from the destruction of their natural enemies,
5. Insecticides have undesirable side effects on nontarget organisms such as parasites and predators; fish, birds, and other wildlife; honeybees and other necessary pollinators; domesticated animals; humans; and crop plants,
6. Insecticides present a hazard to the applicator, and
7. Insecticides reduce and simplify the arthropod component of the agricultural ecosystem.

Integrated pest management (IPM) is the management of insect populations by the use of all suitable techniques in a compatible manner so that damage is kept below economic threshold levels. Principal considerations of the IPM approach to insect management are the agricultural ecosystem, the economic threshold, and the least disruptive program, with some emphasis placed on biological control agents such as beneficial insects.

FIELD CROP INSECTS

ALFALFA INSECTS

The alfalfa weevil is considered to be a serious threat to the production of alfalfa in all areas of Utah. The majority of the damage occurs during the time when the first alfalfa cutting is being produced, but damage by larvae as well as adults may also delay regrowth. Feeding injury is evident by the skeletal appearance of the fully expanded leaflets in the top third of the plants.

OTHER CROP INSECTS

There are numerous insects and insect relatives that damage corn and small grains in Utah. They include: Corn Earworm, Cutworm, Red Spider Mite, Cereal Leaf Beetle, Grasshopper, Russian Wheat Aphid, and a variety of others. A list of major insect pests in Utah appears in Appendix 1.

FRUIT TREE INSECTS

In Utah, most of the important insect pests of fruit trees feed in or on the developing fruit. Examples include the codling moth on apples and the oriental fruit moth on peaches. Damage is caused either by feeding on the surface or by boring inside the fruit to feed. This damage can cause fruit to drop prematurely or make it less acceptable to consumers, thus reducing its market value.

Exception to the fruit feeding pests are those that feed mostly on the leaves, twigs, limbs, or trunks of the trees. Examples are mites, scales, and the peach tree borer. Feeding by these insects can threaten the vitality of trees. Appendix 1 lists the major tree fruit insects in Utah.

VEGETABLE CROP INSECTS

Insects are perpetual pests in vegetables. Some begin feeding as soon as the seedlings emerge, while others attack the growing plant, feeding on both the foliage and the fruit. Many insects build up to very large numbers and are capable of completely destroying various crops.

Appendix 1 lists the major insects that damage Utah vegetable crops.

Healthy, vigorously growing plants are less susceptible to insect attack. Therefore, proper irrigation, fertilization, weed control, and disease control can help hold down insect damage. When insect damage is detected, the insect pest must be correctly identified and the insecticide treatment must provide thorough coverage of the plant to achieve control.

Most insecticides used on vegetables have a short residual, so more treatments may be needed if pest recurrence is a problem. Excessive use of insecticides should be avoided to prevent toxicity to plants and excessive residue on crops. Vegetable pests can be placed into three general groups:

1. **Soil insects** usually attack either the seed at planting time or small, tender plants. However, they may attack larger plants such as carrots or potatoes.
2. **Sucking insects** damage plants by inserting their mouth parts into plant tissue and removing plant juices. Some sucking insects inject toxic materials into the plant while feeding and some transmit disease organisms to plants.
3. **Chewing insects** can cause more damage to vegetables than either soil or sucking insects. They feed on all parts of plants and destroy both foliage and fruit. A wide range of chewing insects attack plants.

RANGELAND INSECTS

Insect management, especially grasshopper control, is an important component of rangeland and pasture management throughout Utah. Grasshoppers are the single most destructive insects found on Utah rangelands. When grasshoppers are present in large numbers they exert a significant destructive influence on rangeland and pasture vegetation.

Grasshoppers have a biotic potential for sudden and explosive population increases.
The severity of a grasshopper outbreak depends on the populations of preceding years, temperature, and moisture conditions at the time of hatching. Factors that restrict the increase of grasshopper populations include unfavorable weather conditions, lack of food, natural enemies, and disease.

Grasshopper outbreaks that exceed a population four times that of the previous year are common. During severe outbreaks, increases exceeding 10 times the previous year's population sometimes occur, resulting in 100 or more grasshoppers per square yard. At this level of infestation, crops and native vegetation will be entirely devoured if control measures are not employed.

Grasshoppers in rangeland habitats have beneficial roles in the rangeland ecosystems. Research has shown that range grasses are stimulated by some grasshopper feeding. The grasses fed on by grasshoppers produced more growth and biomass than plants that were totally protected.

The saliva, droppings, and unknown factors from grasshoppers stimulate plant growth. The uneaten cuttings of leaves and other plant parts should not be considered all waste. This activity produces litter that helps retain soil moisture and provides nutrients for plant growth. Furthermore, grasshoppers are an important animal food source for many omnivorous as well as insectivorous mammals, birds, and fish.

The actual dollar effect of a grasshopper infestation on range livestock productivity varies greatly from year to year. Damage caused by grasshoppers goes beyond actual consumption of forage. They cut grass stems and blades, eating only a part of them; they eat closer to the ground than livestock and feed primarily on the growing part of grasses; and they cut off the seed stalks reducing seed production.

MANAGING RANGELAND INSECTS

Rangelands are a valuable natural resource for livestock production, wildlife habitat, watersheds, recreation, and assorted diverse economic interests that are intimately associated and interdependent. The objective is to save current rangeland forage by reducing infestations to below economic threshold levels. The points to consider when undertaking such a task are:

1. **Economic infestation**: Does current target pest survey data indicate economic-level population densities over most of the proposed treatment area?

2. **Timing**: Is the proposed insecticide treatment going to be applied late enough for most of the pests to have hatched and before egg-laying and/or migration occurs?

3. **Protecting pollinating insects**: Insecticides currently used to control range insects are very hazardous to all bee pollinators. Every effort must be made to protect bees from exposure.

WEED MANAGEMENT

A weed is an unwanted plant or a plant growing in the wrong place. This designation is based on human preferences and requirements. Usually a plant is considered a weed when it interferes with land or water resources or it grows in a location where other plants are desired. Agricultural weeds are divided into two basic groups, grass and broadleaf.

GRASS
Grasses are narrow-leave plants that generally grow upright and have parallel veins in the leaves. Young grass seedlings have one leaf that emerges from the seed. Many grasses have a fibrous root system, while others have rhizomes or stolons. Agricultural producers consider the following grasses to be weeds: Common Sandbur, Barnyard Grass, Green Foxtail, Wild Oats, Jointed Goatgrass, Quackgrass, Johnsongrass, and Wild Proso Millet.

BROADLEAF
Broadleaf plants generally have broad, net-veined leaves. The root systems have either a single taproot or an extensive root structure that spreads both vertically and horizontally. Agricultural producers consider the following broadleaves to be weeds: Field Bindweed, Canada Thistle, Musk Thistle, White Top, Russian Knapweed, Tansy Mustard, and Burdock.

For an extensive publication on the weeds found in Utah, the book "Weeds of the West" may be purchased from Utah State University Extension <www.ext.usu.edu>. If there is a question regarding the proper name or identification of a plant, a specimen can be submitted to a local county extension office for identification.

UTAH LEGISLATION CONCERNING WEEDS AND WEED SEEDS
The Utah Seed Law is aimed at controlling the spread of noxious weed seeds and the noxious weeds. This law applies to agricultural, vegetable, and ornamental seed that is sold, bartered, or distributed in Utah for seeding purposes. Noxious weed seed refers to seeds produced by especially troublesome and detrimental plants that may cause damage or loss to a considerable portion of the land or livestock of a community.

There are two classifications of a noxious-weed seed: prohibited noxious weed seed and restricted noxious weed seed. Seed sold for planting purposes must be clean of all prohibited noxious weed seeds and cannot contain more restricted noxious weed seeds per pound than listed in the rules and regulations in R68-8 and Title 4, Chapter 17. Prohibited or restricted weeds and seeds that fall under the Utah Seed Law (R68-8) and the Utah Noxious Weed Act (Title 4, Chapter 17) can be found in Appendix 2.

PLANT LIFE CYCLES

ANNUALS

Annuals are plants that complete their life cycles in one growing season and can only propagate by seed. Summer annuals germinate in the spring, develop and set seed in the summer, then die before winter. Common summer annuals are Russian Thistle, Redroot Pigweed, Kochia, Lambsquarters, and Barnyard Grass. Winter annuals germinate in the late summer or fall, over winter, and then resume growth in the spring. By summer, they flower, set seed, and die. Common winter annuals are Downy Bromegrass, prickly lettuce, tansy mustard, and wild oats.

BIENNIALS

Biennials require two years to complete their life cycles. These plants develop from seed and grow without flowering the first year. Usually the first year's growth results in a cluster of leaves, or rosette, close to the ground. In the second year, the plant flowers, produces seed, and dies. Common biennials are musk thistle, mullein, burdock, and mallow.

PERENNIALS

Perennials are plants that can live three years or longer. They can propagate by seeds, by runners, from stems above the ground (stolons), or by underground stems that develop roots and leafy shoots (rhizomes). These plants can flower and set seed each year, die back to the ground during the winter, then resume growth in the spring. Common perennials are Canada Thistle, Field Bindweed, Whitetop, Russian Knapweed, and Quackgrass.

WEED MANAGEMENT PLAN

In order to develop a successful weed management plan, the objectives must be clear and practical. The

strategies of this plan involve the techniques of prevention, eradication, and/or management.

PREVENTION
Prevention includes all the measures taken to avoid or delay the introduction and spread of weeds. This will include good farm-management techniques and, if necessary, legislative control. Preventive control measures should be adopted whenever practical and should be the first step in a weed-management program. There are several preventive measures that agricultural producers can take.

1. Always use certified weed free seed.
2. Do not feed grains or hay containing weed seeds.
3. Do not spread manure while weed seeds are still viable.
4. Do not move livestock directly from land where weeds are present to weed free areas.
5. Avoid moving soil and debris from weed infested areas to weed free areas.
6. Make sure agricultural equipment is cleaned before moving it from weed infested areas.
7. Inspect nursery stock for weed seeds and other weed parts.
8. Keep irrigation ditches, fence lines, roadsides, and other non-crop areas free from weeds.
9. Whenever a new weed infestation is identified, especially a small infestation, immediately begin weed control efforts before spread occurs.

Preventive measures can also be carried out through legislative action. Statewide noxious weed control laws can mandate control of troublesome weed species and help stop the spread of noxious weeds within a state. Additional legislative action, such as mandating that farm equipment transported into the state be clean of weed seeds, further helps prevent the spread of weeds.

ERADICATION
Eradication means the complete removal or destruction of the living plants, roots, and seeds from an area. This is practical for small infestations, but it is not practical for the majority of weeds that infest large areas of land. For many weed species, maintenance control programs on an annual basis are necessary because of the duration of seed viability in the soil. For example, field bindweed seeds may germinate after 40 years in the soil. Most weed seeds will stay viable in the soil for longer than five years.

MANAGEMENT
Management is the process of containing and limiting weed infestations. A principle of weed control is to reduce the infestation and minimize the competitive effect on a crop. A weed management strategy is more practical than eradication when dealing with extensive infestations.

WEED MANAGEMENT TECHNIQUES

Weed management techniques include cultural, mechanical, biological, and chemical controls. An integrated weed management (IWM) approach utilizes two or more of these techniques. IWM is the most effective and economical approach to agricultural weed management.

CULTURAL
Crop competition and crop rotation are two cultural controls that can be very effective in weed management and are inexpensive. Competition involves choosing a suitable crop and using the best production methods so the crop outgrows the weed, minimizing the weed growth and spread.

An example of competition is the use of alfalfa to compete with Canada thistle. A dense seeding of alfalfa in the fall with good crop establishment in early spring can help shade, crowd, and ultimately reduce both the vigor and density of Canada thistle. Using a non-residual broadleaf herbicide on the Canada thistle before alfalfa seeding will produce even better results.

The presence of a weed infestation is one of the factors considered in the selection of a rotation crop. A rotation crop should crowd out a weed or allow other methods of weed management such as tillage, herbicides, or fallow to be implemented.

An example of when crop rotation is needed is corn infested with Wild Proso Millet. Control of Wild Proso Millet in corn is very difficult with mechanical means and costly with herbicides. Rotating into beans or onions would allow the use of less costly herbicides or continued mechanical methods throughout the season.

MECHANICAL
Mechanical control includes cultivation, mowing, hoeing, hand pulling, and root plowing. All of these methods involve the use of tools to physically cut off, cover or remove undesirable plants from the

soil. Cultivation or tillage is the most common method of weed control. This method is effective for small annual weeds, but less effective for the larger annuals. Tillage can also be used for controlling perennial weeds. Frequent tillage operations, every 10 to 14 days, for two or more seasons are required for the control of most perennial weeds.

The use of fire is another mechanical method of controlling weeds. Fire can be an effective tool for removing vegetation from ditch banks, roadsides, fence lines, and other areas. Fire can be used in the fall to burn off the trash of dried weeds that are remaining. If the weed seeds are still remaining on the plant, burning can reduce the number of viable weed seeds. Burning does not destroy the majority of seeds that have fallen to the ground.

The use of flooding as a weed management measure temporarily reduces the oxygen concentration in the soil. Seeds need a certain concentration of oxygen to germinate; therefore, use of flooding in the spring could reduce the number of weed seeds germinating. Use of flooding is not practical in many agricultural situations.

BIOLOGICAL

Biological control of a weed may involve using natural enemies, such as insects and plant diseases. Grazing of weeds by livestock is also a form of biological control. Generally speaking, biological control works best on large infestations of a weed. In most agricultural situations, the effectiveness of biological control is limited because of intensive farming practices.

A good example of biological control is the establishment of the seed-head weevil, *Rhinocyllus conicus*, on musk thistle throughout Utah. Another example is the use of sheep to feed on leafy spurge, especially when it is in the seedling stage. Biological controls will not eradicate a weed population, but they can reduce density and size of infestations.

CHEMICAL

Chemical control involves the use of herbicides to kill or inhibit plant growth. The use of herbicides by humans for weed control dates back to the turn of the century, when iron sulfate, copper nitrate, and solutions of sulfuric acid were used. In the 1940s, 2,4-D was developed as a selective herbicide. Since that time, hundreds of herbicides have been developed.

INTEGRATED WEED MANAGEMENT

IWM is the use of two or more weed control techniques in a management program. Often the use of two or more methods will result in better overall weed management. The selection and implementation of weed management techniques depends on ecological, agronomic, and economic factors.

For management of perennial weeds, combined efforts of cultural, mechanical, biological, and chemical methods will produce better results than the use of a single control technique.

RANGELAND WEED AND BRUSH MANAGEMENT

Much like crop producers, good weed and brush management practices are required for livestock producers to maintain and improve the productivity of rangeland. Many of the methods and practices employed for crop production are also effective for range and pasture management.

Nonproductive weeds and brush invade rangeland as the desirable native species are weakened or thinned out by practices or conditions such as overgrazing or erosion. There are several problems that occur when weeds and brush infest pasture and rangeland.

The first problem is the takeover factor. Once weeds and brush become established, they spread rapidly. The yield potentials and carrying capacity of these lands decline.

The second problem is poisonous plant hazards. In many cases, plants that invade abused rangeland are toxic to livestock. In the 17 western states, losses by livestock producers to toxic plants are estimated to be $107 million annually. When considering livestock abortions, birth defects, poor gains, chronic illness, and other problems caused by poisonous plants, the figure is much larger. In the western states, almost nine percent of nutritionally sick animals are ill from eating poisonous plants.

A third problem is the reduction in the efficient use of range when brush takes over. It becomes virtually impossible to manage livestock in areas overgrown with such vegetation. Furthermore, it may be

necessary to increase the number of breeding males in order to maintain acceptable birthrates.

Other sources of infestation or re-infestation include non-range and non-crop areas such as transportation and utility right-of-ways, roadsides, field borders, fence lines, and areas around farm and ranch buildings. It is here that weed seeds often originate and, if not managed, the surrounding lands become infested.

CLASSES OF HERBICIDES

Most herbicides are classified as either organic or inorganic, with most of the compounds being organic. Some of the common classes of herbicides follow:

PHENOXIES
The phenoxy herbicides are widely used in both crop and non-crop areas for control of most annual and perennial broadleaf weeds. Some commonly used phenoxies include: 2,4-D (amine and ester formulations), MCPA, dichlorprop (2,4-DP), and 2,4-DB (Butoxone or Butyrac). The phenoxies are primarily applied as a post-emergence treatment to the foliage of actively growing weeds. Entrance into plants through root uptake is also possible. The phenoxies are primarily plant growth regulators and affect the actively growing tissue of the plant. The ester formulations of the phenoxies are relatively volatile and turn into a gas during hot summer days. Care should be taken not to use them around susceptible broadleaf crops and ornamentals.

TRIAZINES
The triazines are used in a number of crops and in orchards and shelterbelt areas to control annual grasses and broadleaf weeds. Some commonly used triazines include atrazine (AAtrex), simazine (Princep), and metribuzin (Sencor or Lexone). The triazines are often applied as a pre-plant or pre-emergence incorporated treatment. Prometon (Pramitol) is a nonselective pre-emergence and post-emergence herbicide used on non-crop land. The triazines affect plants by inhibiting their ability to photosynthesize. The triazines have been used so extensively in certain crops, such as corn, that resistant weed species have developed. Resistant biotypes of kochia have been identified in Utah.

THIOCARBAMATES
The thiocarbamates are used on cropland and on ornamental plantings for control of annual grass seedlings and broadleaf weed seedlings. EPTC (Eptam) is a commonly used thiocarbamate. The thiocarbamates are applied as a pre-plant, soil incorporated treatment. They inhibit the meristematic growth of plants, such as root and shoot tips. Most thiocarbamates are relatively volatile and must be incorporated into the soil.

UREAS AND URACILS
The ureas and uracils have several similar uses and their modes of action have many features in common. Many of the compounds found in these two classes of herbicides are used at lower rates than other herbicides in crop and noncrop areas for control of annual grass seedlings and broadleaf weed seedlings. Some of the compounds are used at higher rates as a nonselective, bare ground product. Diuron (Karmex) and tebuthiuron (Spike) are commonly used ureas and bromacil (Hyvar) is a widely used uracil. These compounds are primarily used as soil applied, pre-plant or pre-emergence herbicides, but they also provide post-emergence control for certain plants. The ureas and uracils affect plants by inhibiting their ability to photosynthesize.

BENZOICS
The benzoic acid herbicides are used in both crop and noncrop areas for control of numerous broadleaf weeds and annual grasses. A commonly used benzoic is dicamba (Banvel or Clarity). The benzoic herbicides are effective when applied either foliar or to the soil. The benzoics are plant growth regulators similar to the phenoxies. They affect the actively growing tissues of plants.

ACETANILIDES
The acetanilide herbicides are used in numerous crops and in some ornamentals for control of many annual grasses and broadleaf weeds. Common acetanilides include alachlor (Lasso), acetochlor (Harness or Surpass), metolachlor (Dual), and pronamide (Kerb). The acetanilides are used as selective herbicides in crops such as corn and sorghum. They are applied as either a pre-emergence or pre-plant treatment.

SULFONYLUREAS
This class of herbicides is one of the most recent to be developed. The sulfonylureas are highly active compounds used at extremely low rates. They are used mainly to control many broadleaf species in small grain crops, pastures, and non-crop areas. Commonly used sulfonylureas include chlorsulfuron (Glean and Telar), triasulfuron (Amber), sulfometuron (Oust), and metsulfuron

(Ally and Escort). These compounds are usually applied as foliar treatments; however, they also control newly emerging broadleaf seedlings. Chlorsulfuron and sulfometuron are sulfonylureas that are more persistent in nature and will carry over into a second year when applied in high-pH soils. Care must be taken when using these compounds around certain crops such as corn, sugar beets, and potatoes. Extremely low residues from wind drift or in wind blown soil can cause significant crop loss.

IMIDAZOLINONES
A new and important herbicide family is the imidazolinones. It includes imazethapyr (Pursuit), imazamethabenz (Assert), and imazapyr (Arsenal).

HERBICIDES BY USE

Herbicides can be conveniently classified by their selectivity, which is how they affect the target and nontarget vegetation. They also may be classified by use, whether they are applied to the soil or foliage of the plant. Herbicides affect plants in different ways. Some herbicides work strictly by contact with the leaf and stems of the plant, while others may be taken up by the roots or leaves of a plant and translocated throughout the plant, acting systemically. Some herbicides used at lower rates may help regulate the growth of the plant and production of the seed, while at higher rates, they will kill plants.

SELECTIVE HERBICIDES
The primary role of a selective herbicide is to remove unwanted vegetation (weeds)
from an area, whether it be in a crop, range or pasture, without affecting the surrounding vegetation. Some selective herbicides such as 2,4-D, dicamba and picloram are applied to the foliage of the plant, while other herbicides such as atrazine, trifluralin, and oryzalin are applied to the soil.

NONSELECTIVE HERBICIDES
Nonselective herbicides are chemicals that are phytotoxic to most plant species. These compounds are generally used where either no vegetation is wanted, such as along transportation and utility rights-of-way or ditches, or where it is necessary to destroy the top growth of a crop such as with potatoes. Compounds like glyphosate, which have no soil residual, are used in crop systems as a chemical fallow treatment. Commonly used nonselective herbicides include glyphosate, imazapyr, bromacil and paraquat. When using the longer-residual non-selective herbicides such as bromacil, diuron or tebuthiuron, extreme caution should be taken around crops, trees or water.

Do not apply any of these herbicides on sloping land where there is potential of washing the herbicide into nontarget vegetation or water. Treated soil should not be moved or used for other purposes unless tested and found free of residue. Care must be taken when applying any herbicide. Most selective herbicides can become nonselective as a result of over application.

CONTACT HERBICIDES
Contact herbicides are applied to the foliage of plants. These herbicides affect only the part of the plant they contact. Usually complete coverage of the plant is necessary for good control. Most contact herbicides are nonselective. Bromoxynil, paraquat, and diquat are commonly used contact herbicides.

TRANSLOCATED HERBICIDES
Herbicides that move from one part of the plant to another such as from the leaf to the roots are translocating or systemic herbicides. Herbicides that move from the leaf surface and flow to the root through the phloem follow the same pathway as sugar that is formed by photosynthesis. Herbicides that are absorbed by the root enter the xylem and move throughout the plant, following the same path as transpirational water.

Translocating herbicides may be either soil or foliar applied or both, depending on the herbicide and its route of action. Some herbicides will move exclusively through either the foliage or the roots, while other herbicides can move equally through both systems.

Translocating herbicides are an important tool in controlling perennial weeds, which have extensive underground root systems that are hard to kill. Some commonly used foliar-applied herbicides which translocate into both foliage and roots include: MSMA, glyphosate, dichloprop, 2,4-D, dicamba, picloram, and chlorsulfuron.

Commonly used soil-applied herbicides that primarily translocate through root uptake are simazine, diuron, pronamide, and EPTC. A number of the triazines and thiocarbamates will translocate through both processes; however, they primarily

work through root uptake because of the recommended method of application.

PLANT GROWTH REGULATORS

Plant growth regulators (PGR) are herbicides used for regulating or suppressing the growth of a plant and/or its seedhead production. Some of the PGR herbicides such as mefluidide (Embark) strictly suppress the growth and seedhead production of certain grasses and do not have any phytotoxic effects on other grasses or broadleaf plants in general. Sulfometuron (Oust) is a herbicide that causes growth and seedhead suppression on certain grasses and controls many annual broadleaf weeds as they germinate in the soil. An example of a herbicide used as a growth suppressant of many brush species is fosamine ammonium (Krenite). These herbicides are generally applied to the foliage of the plants.

FACTORS AFFECTING FOLIAR APPLIED HERBICIDES

BIOLOGY OF WEEDS

Grass and broadleaf weeds go through stages of growth in which they are more or less susceptible to herbicides. Proper timing of a herbicide application is important for effective plant control. The basic stages of plant growth are seedling, vegetative, bud and flowering, and maturity. These stages vary between annual, biennial, and perennial plants.

Seedlings

Whether looking at annual, biennial or perennial weeds, the seedling stage of growth is the same, they all start from seed. The weed seedlings are small and tender, so less energy is required for control at this stage of growth than at any other. This is true whether mechanical or chemical control is used. Herbicides that are foliar or soil applied are usually very effective at this stage of growth.

Vegetative

During the vegetative stage of growth, energy produced by the plant goes into the production of stems, leaves, and roots. Control at this stage is still possible but sometimes harder than at the seedling stage of growth. At this stage, a combination of cultivation, mowing, and herbicide applications offer effective control.

ANNUALS

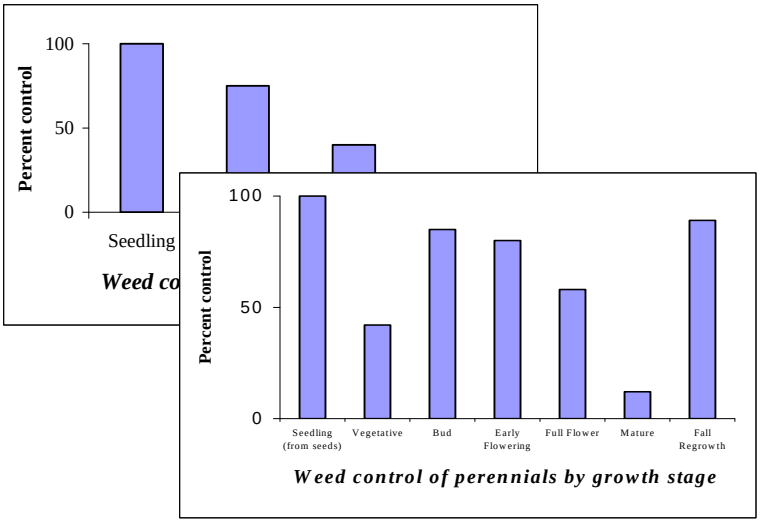
Flowering

When an annual plant changes from the vegetative to the flowering stage of growth, most of its energy goes into the production of seed. As plants reach this more mature stage, they are usually much harder to control by chemical methods.

Maturity

When an annual plant has produced seed, it has completed its life cycle. Once seeds are produced, mechanical or chemical control methods are not effective, since neither method will destroy the seed.

BIENNIALS



Vegetative

Biennials are plants that complete their life cycles in two years. Most biennials develop a rosette, a cluster of crowded leaves close to the ground, in their first year. The rosette can be seen in the fall and in the spring of the following year. Best control of biennials with the use of herbicides can be achieved during this growth stage.

Bud to Flowering

Effective control of biennials with herbicides can be achieved when the plant is in the bud to early flower stage.

Maturity

When a biennial plant has produced seed, it has also completed its life cycle, just like the annual plant. Mechanical or chemical control measures would once again not be effective at this stage of growth, since the seeds would not be affected.

PERENNIALS

Vegetative

Most systemic foliar herbicides translocate within plants in much the same pattern as sugars. The most effective herbicide applications coincide with the time when the greatest abundance of sugars is being translocated to the roots. When the plant is small, much of the energy used to produce stems and leaves comes from the sugars and starches stored in the underground roots and stems. Herbicide treatment at this time provides only fair results. As the plant grows, more energy is produced in the plant leaves. Some of these nutrients are moved to the underground parts for growth and storage. Herbicide treatment at this time provides fair results.

Bud to Flowering

At this stage, the plant's energy goes into the production of flowers and seeds. Food storage in the roots begins during this stage and continues into maturity. Chemical control is generally more effective at the bud stage than at the flowering stage. This is an excellent time to apply a systemic foliar herbicide.

Maturity

During the period between the production of seed until the fall regrowth, perennial plants go into a time of senescence or aging. The plant is not feeding its root or growing, and therefore chemical control at this time is not very effective. When fall approaches, the plant becomes active again and starts sending nutrients (food reserves) down to the root to store for the winter. Fall regrowth is another excellent time to chemically treat perennial weeds, since the plant will readily translocate the herbicide down throughout the root.

PHYSICAL CHARACTERISTICS OF PLANTS AFFECTING HERBICIDE EFFECTIVENESS

The physical characteristics of plants such as leaf shape, cuticle layer of the leaf surface, and leaf hairs affect the ability of herbicides to gain entrance into the plant. By considering each factor, more effective control is achieved.

Leaf Shape

Leaf shape affects the amount of herbicide that may enter the plant. Herbicide sprays tend to bounce or run off plants with narrow, upright leaves such as grasses. Most broadleaf plants have wide smooth leaf surfaces that are parallel to the ground and hold the herbicide spray on the leaf surface.

When spraying grasses or other narrow leafed weeds, some herbicide labels may suggest adding a surfactant (spreader or sticker) to the spray to help the spray solution to adhere to the leaf surface and therefore increase the effectiveness of the herbicide.

Cuticle Layer

All plants have a waxy leaf surface called a cuticle. The cuticle restricts the movement of water and gasses in and out of the leaf. The cuticle thickness will vary within the same species, depending on the environmental condition each plant is exposed to. Plants growing in the shade often have thinner cuticles than those growing in the sun and younger leaves usually have thinner cuticles than older leaves.

The waxy cuticle layer affects the absorption of the herbicide by the plant. The herbicide must penetrate the leaf surface to be effective. A leaf with a thin cuticle layer allows the spray solution good contact with the leaf surface with resulting absorption. However, on a leaf with a thick waxy cuticle layer, the spray solution tends to stand up in droplets and has more difficulty penetrating the waxy cuticle layer. Adding a nonionic surfactant (wetting agent) to the spray solution (if instructed to do so on the label) is important when treating any plant that has a thick cuticle layer.

Leaf Hairs

Hairs on the leaf surface also tend to keep the spray solution from making contact with the leaf surface. Droplets are formed and are suspended by the hairs. Adding a nonionic surfactant (wetting agent) to the spray solution (if instructed to do so on the label) is

important when treating any plant that has leaf hairs. A nonionic surfactant will break the surface tension of the water droplets and improve the spread of the spray solution over the leaf surface. Many foliar herbicides already have a surfactant added to the formulation.

FACTORS AFFECTING SOIL APPLIED HERBICIDES

SOIL CHARACTERISTICS

The physical and chemical characteristics of the soil as well as the climatic conditions will determine the effectiveness of a soil applied herbicide, the persistence of the herbicide in the soil, and the potential movement of the herbicide through the soil (leachability).

One of the properties of soil particles, as well as herbicides, is that they vary widely in their polarity or magnetism. Both soil particles and herbicides can either be negatively or positively charged or neutral (no charge). Like charged particles tend to repel each other while oppositely charged particles tend to attract each other or bind together. Neutral particles are neither attracted nor repelled by other particles except through surface tension. Herbicides that have neutral polarity tend to move through the soil profile more readily.

Soil particles vary in the number of charge sites they may have. Sand particles have few charge sites, while clay particles and soils containing a lot of organic matter have many charge sites. Knowing the texture of the soil and the percentage of organic matter at a herbicide application site is important because they greatly affect the persistence of the herbicide in the soil and the ability of the herbicide to move in the soil. The type of soil particle not only determines its binding ability but also the pore space or water-holding capacity.

SOIL TEXTURE

Soil textures are categorized into three groups.

1 Sands and sandy loams are referred to as light- or coarse-textured soils.

2. Loams, silt loams, and clays are referred to as medium-textured soils.

3. Clay loams, silty clay loams, and clays are referred to as heavy- or fine-textured soils.

Soil texture can be determined by a soil test. Contact a local county extension office or a Natural Resources Conservation Service (NRCS) Office for information on how to collect soil samples. Detailed soil maps have been developed by the NRCS for most counties in Utah. Herbicide labels have recommended rates of application based on the soil texture.

The texture of soil basically is determined by the percentage of sand, silt, and clay in it. Sand particles are coarse and relatively large, and they have few charge sites. They have large pore openings between the particles that allow water to move down through the soil profile rapidly. The combined characteristics of few charge sites and large pore openings make sandy soil the most permeable (the ability for water and herbicides to move with least resistance through the soil column). The risk of groundwater contamination is greatest in sandy soils.

Silt has more charge sites than sand and is finer in particle size; thus it is less porous than sand. Silty soils tend to hold more water and herbicide than do sandy soils, but not as much as clay soils.

Clay particles are fine with many charge sites. Water and herbicides tend to be bound up in clay soils. These soils act as a barrier to the flow of herbicides through the soil profile. Soils that are high in clay content require more soil-applied herbicide for weed control than do sandy soils.

Organic matter has many more negative charge sites than even the finest clay particles. In addition to the herbicide molecules tied up on the organic matter, there are also particles of water, sodium, calcium, and ammonia.

TEXTURE (CLAY)

Soils that are high in organic matter and clay content will hold a herbicide for a longer time than sandy soils. Herbicides are bound to the organic matter and clay particles and released so slowly that the chemical may not be effective as a herbicide. Herbicide persistence is greatest in soils with high organic matter and clay content.

HERBICIDE PERSISTENCE

The physical characteristics of a herbicide (polarity) and soil texture greatly affect the persistence of a herbicide in the soil. Other factors that affect herbicide persistence include the rate of application, microbial and chemical decomposition, solubility of a herbicide, and precipitation. These factors also affect how deep a herbicide will leach in soil.

Herbicides vary greatly in their ability to be soluble or uniformly dissolved in water. The greater the solubility of the chemical, the greater the potential for leaching deeper into the soil column. Soil microorganisms such as algae, fungi, and bacteria live in the soil and use organic matter as a food source. Organic herbicides are decomposed through this feeding process. Chemical decomposition of some herbicides occurs through chemical reactions such as oxidation, reduction, and hydrolysis. Annual rainfall affects how long a herbicide will persist in the soil, especially in the top one to four inches, where most weed seeds germinate. Herbicides tend to persist longer in dry areas.

HERBICIDE SELECTION

CROP KNOWLEDGE

A thorough knowledge of the crop where weeds are to be controlled is essential for weed control and crop protection. Selection of the proper herbicide, appropriate application rate, and the best timing for treatment depend on the crop being grown. A thorough knowledge of the herbicide labeled for use with a particular crop is also important. Herbicide labels provide detailed information for proper and safe use. A herbicide label provides the best guidelines for successful weed management.

CROP ROTATION

When selecting a herbicide, thought should be given to the crop rotation planned for the next year. A number of herbicides stay active in the soil for six months or more and will kill certain crops even when present in extremely low amounts. Application of a herbicide may limit which crop can be planted the following year. The following are two situations where crop rotation is limited. If atrazine is used in corn, a different crop cannot be planted for two years. If Banvel is used in grain or corn at fairly heavy application rates, especially in the fall, it would not be possible to rotate to broadleaf crops, such as beans, potatoes, or alfalfa the following spring. Crop rotation limitations are clearly stated on the labels of the herbicides registered for use in cropland. Herbicide selection is an important consideration when crop rotation is scheduled.

SURROUNDING VEGETATION

When choosing a herbicide to use for weed control, consider the vegetation that is close to the application site. Take precautions so that the herbicides used will not drift to nontarget areas. The contamination of nontarget vegetation by herbicides can occur three ways: by wind drift, physical movement, and volatilization.

Herbicide drift occurs when spray droplets are carried away from the application area by air movement. Smaller sized droplets have a greater potential for wind drift. Fog and mist applications present the greatest hazard. The distance a sprayed herbicide can drift depends on the speed of the wind, height of the nozzles above the ground, and size of the spray droplets.

Physical movement of a herbicide can occur when soil with herbicide particles bound to it is blown from the target site. This type of herbicide movement is more likely to happen when a herbicide application is made to bare ground. When applying any herbicide that is extremely active at low rates (such as the sulfonylurea herbicides) the applicator must be careful around non-target vegetation.

Volatilization or vaporization occurs from the evaporation of the herbicide after it hits the soil or plant surface. Certain herbicides such as the 2,4-D ester formulation and dicamba will vaporize during hot summer days. The movement of such vapor with wind currents may injure sensitive vegetation. If a herbicide volatilizes easily, precautions for use during hot weather will be stated on the label.

Applicators should follow the label directions concerning herbicide use and restrictions during hot

weather. Recommendations found on herbicide labels for spray applications include:

- Mix and apply herbicide formulations having a low volatility,
- Apply herbicides using the lowest practical spray pressures,
- Apply herbicides using the largest practical spray droplet size,
- Apply herbicides when wind speed is low, and
- Do not apply herbicides during a temperature inversion (when air is coolest at ground level, gets warmer up to a certain height, and gets cooler from that point up.

III. AGRICULTURAL PLANT DISEASE MANAGEMENT

PLANT DISEASE MANAGEMENT 18

PLANT PATHOLOGY 18

NONINFECTIOUS AGENTS 19

INFECTIOUS AGENTS 20

RECOGNIZING PLANT DISEASES 22

DEVELOPMENT OF PLANT DISEASES 23

PLANT DISEASE MANAGEMENT 24

PLANT DISEASE MANAGEMENT

Pesticide applications, if economically and biologically justified, can reduce losses caused by plant pathogens (infectious agents) in field and vegetable crops, fruit trees, ornamentals and turf. Pesticides provide no benefit if applied to plants damaged by noninfectious agents such as nutrient imbalances, weather extremes, chemicals, and cultural practices. Successful control of plant pathogens through the use of pesticides is dependent upon the following conditions.

1. An infectious agent is causing the disease,
2. Application of a pesticide is justified,
3. An appropriate pesticide is selected, and
4. The rate, method, timing, and frequency of pesticide application are correct.

PLANT PATHOLOGY

The growth and yield of plants depend on the availability of nutrients and water in the soil where they grow and on favorable environmental factors such as temperature, moisture and light. Anything that affects the health of plants is likely to affect their growth and yield. Plants suffer from diseases that are similar in many ways to those affecting animals and humans.

A plant disease can cause disturbances that prevents the normal development of a plant and reduce its economic or aesthetic value. A disease interferes with the normal function of some part of the plant, resulting in reduced quality and/or yield. A list of major plant diseases appears in Appendix 3.

Diseases are caused by noninfectious agents that include environmental, nutritional and chemical imbalances, and by infectious agents including microorganisms and parasitic plants. Plant pathology is the study of four topics: (1) the noninfectious and infectious agents that cause diseases in plants, (2) mechanisms by which these agents produce diseases, (3) interactions between the disease-causing agent and diseased plant, and (4) methods of preventing or managing the disease and its damage.

If a disease has not been previously identified or is not well known, then the diagnosis of a causal agent must involve four criteria:

1. The causal agent must be consistently associated with the disease,
2. The causal agent must be accurately identified or isolated in pure culture,
3. The symptoms found in the diseased plants must develop in healthy plants when they are inoculated with the pathogen, and
4. If caused by a biotic agent, the pathogen isolated in the second criteria must be isolated from plants inoculated in the third criteria.

NON-INFECTIOUS AGENTS

Plant diseases may be caused by a change in the environment such as an excess or deficiency of some factor needed for growth or by some harmful substance in contact with the plant. Pathogens are not present in the noninfectious (abiotic) diseases and therefore cannot be transmitted from one plant to another. These diseases may occur during plant growth and handling, from germination to maturity; and in storage or processing. Symptoms of noninfectious agents are often confused with those caused by infectious (biotic) agents, and they range from slight to severe as plant tissue exhibits localized to general damage.

Extremes in temperature, moisture, or light are often unfavorable for plant growth. Nutritional deficiencies and excesses cause disease like problems that must be correctly identified if they are to be corrected. Chemically induced plant disease may result from improper soil pH, improper use of fertilizers, pesticides, chemical spills, runoff and air pollution. Cultural practices may compact soil or mechanically wound plant tissue, creating unfavorable conditions for plant growth. These conditions may predispose plants to infection by biotic agents.

Plants require a certain balance of nutrients or mineral elements for normal growth. Nitrogen, phosphorus, potassium, calcium, magnesium, and sulfur are needed in large amounts and are called major elements. Iron, chlorine, molybdenum, manganese, copper, zinc, and boron are usually needed in very small amounts and are called trace or minor elements. When one or more of these nutrients are deficient or excessive, plants become diseased and exhibit various symptoms that may appear on the roots, stems, leaves, flowers, fruits, and/or seeds.

These symptoms include:
1. Reduction of growth and yield,
2. Tissue discoloration and burning (colors of white, light green, yellow to brown),
3. Curling and distortion of leaves and other plant structures, and
4. Wilting, and/or death.

Nutrient imbalances can be identified by analysis of soil and tissue samples at a qualified soil-analysis laboratory. Based on the test results, fertilization programs can be devised to prevent or correct the nutritional problem.

Table 1. Nutrient Deficiencies in Plants

Nutrient	Symptoms
Nitrogen	Light green color, lower leaves turn yellow to brown, poor growth
Phosphorus	Bluish-green leaves, lower leaves light bronze
Potassium	Yellowing of older leaves and brown tips, scorched and spotted margins, dieback if severe
Magnesium	Older leaves affected first, mottled or yellowed, then reddish, tips and margins of leaves cup upward, drop
Manganese	Yellow leaves, major veins remain green and checked
Iron	Young leaves are yellow, major and minor veins green, brown spots
Zinc	Intravenous yellowing, brown, short internodes.

Most plants will not grow well in acid (pH less than seven) or alkaline (pH greater than seven) soils when the levels are extreme. In acid soils, mineral salts are more soluble and so concentrated that they are toxic to plants or interfere with absorption of other necessary elements. Symptoms of mineral deficiency then develop. Excessive amounts of certain salts raise the soil pH and cause alkali injury such as burning (tan to brown discoloration) of leaf edges. In alkaline soils, minor elements like iron and zinc are not available to the plant resulting in severe growth reduction. Soil tests can help identify

these types of problems and provide guidelines for their management with future crops.

Weather extremes can damage plants at various stages during their development and maturity. Low temperature will injure plants by causing ice formation between and/or within cells that, in turn, injures membranes and other cell components. Late spring and early fall frosts damage and kill tender plants, buds, leaves, flowers, fruits, and seeds. Damaged tissue wilts, turns brown to black, and dies. Spring frost damage can usually be avoided by planting on recommended dates. Proper shading, covering, mulching, irrigating, fertilizing, and heating help reduce the damage if cold temperatures are not too extreme.

Leaf scald or sunburn occurs during periods of high temperature following periods of rapid plant growth, especially after rainy and cloudy weather. Large, irregular, water soaked, or dead areas may form on sun exposed portions of succulent leaves or fleshy fruits and vegetables, including apples, tomatoes, onions, and potatoes. Excessive light, drought, high winds, and the low relative humidity that usually accompanies high temperatures all intensify hot weather injury. Little can be done to decrease the effect of these damaging conditions. Reducing soil compaction, crop irrigation, and the planting of varieties resistant to heat stress are the best ways to reduce high temperature damage.

Moisture extremes can damage any type of plant. Too much or too little water will cause injury. During the sensitive stages of plant growth, flowering and fruit production, the correct amount of moisture is important. The first symptom of water shortage in plants is wilting of tissue that may recover during the night. If the water stress continues, plants become dwarfed and stunted. Leaves yellow or redden, begin to die along the tips and margins, and finally drop off.

Other plant parts can be similarly affected, and maturity may even be delayed. Plants may suffer injury when soils become flooded, are water logged, or poorly drained. The plants cannot get enough oxygen for normal growth or they become infected by soil-borne pathogens. Flooding symptoms can include wilting, yellowing, stunting, and death.

Phytotoxic chemicals can damage plants, especially when used improperly. Air pollution from machinery and industry can drift long distances and damage sensitive tissue. Such damage will cause bronze to brown flecking of leaf tissue and tips. One of the common causes of chemical damage is a herbicide applied at a rate too high for soil conditions. This is especially true if wet and cool conditions occur for prolonged periods after planting and/or if soils are compacted and poorly drained. Sensitive roots and growing points may be exposed to toxic levels of the pesticide, solvent, diluent, or carrier. Temperature and humidity affect the severity of the damage, which may include stunting of roots and plants, distortion or discoloration of leaves and other plant organs, yield reduction, and tissue and plant death.

The most effective way to prevent chemical injury is to apply the correct pesticides at the appropriate rates and use methods to reduce drift and contamination of soil and water. Management recommendations also include following an appropriate crop rotation and planting date, planting less-sensitive varieties,
and improving soil conditions and drainage.

INFECTIOUS AGENTS

Diseases caused by infectious agents (plant pathogens) are characterized by their presence on or within plants. The detection and identification of plant pathogens may be accomplished by examination with the naked eye, with a magnifying lens, by microscopic viewing, and/or by laboratory isolation. If a pathogen is not located on the surface of the diseased plant, then additional symptoms and presence of the pathogen may be found inside the plant. Examinations should be done at the margins of affected tissue, in or near vascular tissue, or at the base of the plant such as in its roots.

The general classes of plant-infectious agents that cause plant diseases are parasitic plants (dodder, for example), nematodes (alfalfa-stem nematode), fungi (white mold of beans), bacteria (black leg of potato), phytoplasmas (pear decline), and viruses and viroids (barley yellow dwarf virus). Quite often, a plant is attacked by two or more pathogens, often in combination with a noninfectious agent that may cause additional stress or predisposition to infectious agents.

PARASITIC PLANTS

Parasitic plants are higher plants that reproduce by seed. Most of the parasitic plants have modified root-like structures that attach to plant tissue to get nutrients and water, thereby weakening the host and reducing its productivity. Examples of parasitic

plants include dodder, and leafy and dwarf mistletoes. Dodder can affect many crops, including alfalfa, onions, and potatoes.

Control recommendations include using clean seed and equipment to prevent parasite introduction, crop rotation, restricting movement of livestock between fields, and herbicide applications.

NEMATODES

Nematodes are small (one-fiftieth to one-fourth-inch long), eel-like worms that feed on plants by means of a miniature hypodermic-like structure called a stylet, which is used to suck liquid nutrients out of plant cells.

Females of some species become swollen at maturity and have pear shaped or oval bodies. Nematodes reproduce by laying eggs that hatch as larvae or juveniles. The larvae develop through a series of four molts, where the outer skin is shed, until they become adults. Such nematodes can complete their life cycle in less than 30 days. Some nematode species damage plants primarily by feeding on the outside (ectoparasites), while others (endoparasites) enter and feed from within the plant tissue such as in roots. Nematodes cause damage to plants by injuring cells, removing cell contents, and/or changing normal plant growth processes.

Symptoms of nematode infestation include poor growth, reduced yield and quality, stunting, yellowing, and wilting of plants that cannot get enough water and nutrients. Nematodes may also interact with other pathogens (synergism) to cause more damage than either organism individually. Nematodes can act as wounding agents (predispose roots to soil borne fungal and bacterial pathogens), host modifiers (enzyme and hormone changes in plant tissue), and vectors (of viruses, for example).

Control recommendations include crop rotation, using clean equipment, irrigating with non-contaminated water, biological agents, resistant varieties, and pesticide (nematicide and fumigant) applications. Nematodes are a minor problem in Utah, except for the alfalfa stem nematode.

FUNGI

Fungi (singular: fungus) are small, threadlike organisms composed of tiny filaments called hyphae. Individual hyphae are composed of strands of simple microscopic cells. A mass of branched and intertwined hyphae is collectively called mycelium. Some fungi grow inside plant tissue or organic debris and cannot be seen unless magnified. Other fungi produce visible mildew, molds, and mushrooms. Most fungi produce microscopic spores, which are often spread between plants by wind, water, soil, machinery, animals, or humans.

Spores land on a plant and germinate by producing a germ tube. Hyphae then develop and penetrate the plant surface directly or through natural openings (stomates) and wounds. Fungi damage plants by producing toxins, enzymes, or growth-regulating substances that alter or destroy plant tissue. Diseases include leaf spot, blight, canker, dieback, root rot, damping off, basal stem rot, soft and dry rots, scab, stunting, galls, wilt, rust, mold, and mildew. About 8,000 species of fungi can cause plant diseases and all plants can be attacked by some kind of fungus. Some fungi can grow and multiply only on a living host, while others grow and multiply on dead organic matter as well as on living plants.

Control recommendations include crop rotation, sanitation of previously infected debris, selecting clean seed and transplants, using clean water and equipment, scheduling planting to reduce exposure during favorable weather, utilizing biological agents, selecting resistant varieties, and applying fungicides.

BACTERIA

Bacteria (singular: bacterium) are microscopic, single celled organisms that possess rigid cell walls, contain cytoplasm, have no roots, stems, or leaves, and contain no chlorophyll. Some bacteria have long, slender, hair like coiled appendages called flagella that propel the organism through water. Bacteria reproduce by a process called binary fission in that one cell divides into two cells (possibly every 20 to 30 minutes). Thousands of bacteria can occupy a single drop of water. The rapid multiplication of bacteria and production of toxins and enzymes that alter or destroy plant tissue contribute to the damage caused by bacteria. They enter plants through wounds or natural openings. Symptoms include leaf spots and blights, soft rots, wilts, scabs, cankers, and overgrowths.

Control recommendations include crop rotation, sanitation, selecting clean seed and transplants, using clean water and equipment, utilizing biological agents, selecting resistant varieties, and applying pesticide (antibiotics, bactericides).

PHYTOPLASMAS

Phytoplasmas are small, single-celled organisms that occur inside plant phloem cells. Phytoplasmas do not have rigid cell walls. They assume various shapes and are enclosed by a triple-layered cell membrane. Many diseases caused by phytoplasmas, were originally believed to be caused by viruses (yellows). Phytoplasmas are spread between plants by vectors such as leafhoppers. Phytoplasmas can also be spread in infected plant parts. Symptoms include stunting, proliferation of shoots and roots, yellowing or reddening of foliage, abnormal flowers, and eventual decline and death of the plant.

Control recommendations include crop rotation, weed control of alternate hosts, sanitation of previously infected debris, transplanting clean stock, insect-vector control, resistant variety selection, and pesticide treatment (tetracycline injection) of infected planting stock for phytoplasma diseases.

VIRUSES AND VIROIDS

Viruses and viroids are very small particles composed of nucleic acid and protein. They can be seen only under an electron microscope. Viruses that infect plants are generally spherical or rod-shaped. Nucleic acid (usually ribonucleic acid or RNA) composes the center of virus particles and is surrounded by a protein coat. Viruses cause diseases in plants by diverting energy and structural components, normally used for plant growth, into reproductive processes for the virus. Viruses are spread between plants by insect vectors (aphids, leafhoppers, thrips, whiteflies), nematode vectors, infected plant parts. man, and machinery. Viroids are smaller than viruses. They act like viruses, but the infectious particle is simply a strand of RNA and contains no protein. Symptoms of viruses and viroids include stunting, local lesions, ring spots, mosaics, yellowing, pitting, and distortions of leaves and other plant parts.

Control recommendations include crop rotation, weed control of alternate hosts, sanitation of previously infected debris, using clean transplants and seed, insect-vector control, resistant variety selection, and heat-treatment of planting material.

RECOGNIZING PLANT DISEASES

Plant diseases are initially diagnosed or suspected by the presence of characteristic signs and/or symptoms that are associated with a particular disease or disease complex. Examples are visible masses of hyphae and spores such as mildew, mold, rust, and smut, or other structures that might include white-mold sclerotia.

Symptoms of disease may appear as infection or injury of the plant and may include stunting, dead or rotten spots on plant parts, discoloration, swelling, blight, wilting, and water-soaking. A list of Utah's major plant diseases appears in Appendix 3.

NECROTIC SYMPTOMS

1. **Leaf spots** - localized lesions on host leaves consisting of dead and collapsed cells; lesion color may range from white to yellow to black, depending on the disease; the dead center of a lesion may drop out, leaving a shot hole; chlorosis refers to a yellow-to-green color; necrosis usually refers to dead tissue with a white, tan, brown, or black color
2. **Blight** (scorch, firing, blast, scald) - general and rapid browning of plant parts resulting in their death
3. **Canker** (pitting) - a localized wound or necrotic lesion often sunken beneath the surface of the stem or tree trunk
4. **Dieback** - extensive necrosis of plant parts beginning at their tips and advancing toward their bases
5. **Root rot** - disintegration or decay of part or all of the root system
6. **Damping off** - rapid death and collapse of very young seedlings before or after emergence
7. **Basal stem rot** - disintegration of the lower part of the plant
8. **Soft rots** (leak) **and dry rots** - a wet or dry disintegration of plant parts; may include localized soft rotting or water soaking of tissue
9. **Scab** - localized, slightly raised or sunken, cracked lesions usually on the fruit
10. **Decline and stunting** - poor plant growth; leaves are often small, brittle, and yellow or red; some defoliation and dieback may be present

DISTORTION SYMPTOMS

11. **Clubroot** - enlarged roots that appear like clubs or spindles
12. **Galls** - usually small plant portions such as root hairs become enlarged
13. **Warts** – wart-like protuberances on tubers and stems
14. **Witches'-broom** - profuse upward branching of plant parts
15. **Leaf curl** - distortion, thickening and curling of leaves

OTHER SYMPTOMS

16. **Wilt** (flagging) - usually a generalized but secondary symptom where leaves or shoots lose their turgidity and droop because of a disturbance in the vascular system of the root or stem
17. **Rust** - small lesions on leaves or other plant parts containing masses of fungus spores that are white, orange, red, brown, or black
18. **Mildew** - chlorotic or necrotic areas on plant parts usually covered with white mycelium and spores of a fungus
19. **Mold** - any profuse or woolly fungus growth on damp or decaying matter or on surfaces of host tissue

DEVELOPMENT OF PLANT DISEASES

For a plant disease to exist, a pathogen, susceptible host plant, and favorable environment must be present and interact over a period of time. Disease development in cultivated plants is also greatly influenced by human input. There are many possible combinations of time, pathogen, host, and environment.

The term "**disease cycle**" is used to describe the relationship of a pathogen to its host in an environment and the development of a disease over time. It involves survival of the pathogen during periods that are not favorable for disease development, dispersal of the pathogen to its host, growth of the pathogen on or in plants, development of disease symptoms, and, finally, pathogen survival to complete the cycle. The study of survival and spread of pathogens and disease development in a population of plants over time is called **epidemiology**.

There are many interactions of temperature, moisture, wind, light, plant nutrition, soil type, soil pH, and cultural practices that contribute to disease development. Not all pathogens and the diseases they cause respond similarly to the same set of environmental conditions. Many diseases develop at temperatures most favorable for pathogen development but unsuitable for the host. The occurrence of disease, especially foliar problems in semi-arid areas, is often closely correlated with the amount and distribution of irrigation or rainfall. Nutritional imbalances, either excesses or deficiencies, may stress root systems or provide excess foliage that favors specific pathogens. Soil compaction, chemical damage, and timing of various agronomic practices such as planting, cultivating, irrigating, or harvesting can increase or reduce various pathogens and their disease development.

Many pathogens can survive in the absence of a susceptible host during conditions that are unfavorable for disease development. Pathogens of annual plants may survive from one growing season to the next in alternate hosts, plant debris, seed, or soil. Many pathogens of perennial plants survive in infected tissue of the host plant or in propagating material. When conditions are favorable, these pathogens begin to grow and spread to susceptible plants or tissue.

Pathogens are usually spread by wind, water, soil, in plant parts, or by vectors such as insects or humans. Some bacterial cells and fungal spores can be blown hundreds of miles, while other pathogen structures are dispersed only a few inches or feet from their point of production or survival. Winds strong enough to blow dust particles have enough power to carry insects, nematode eggs, and billions of invisible pathogens capable of causing disease outbreaks throughout and between fields and regions. Rainwater and runoff are also major transporters of pathogens.

The process whereby a pathogen (inoculum) comes in contact with the host is called **inoculation**. For disease to develop, the pathogen must penetrate the host, invade tissue, grow, and become established within the infected host. The time between inoculation and symptom development is known as the **incubation period**, which may vary from a few days to weeks depending on the host, pathogen, and environment. Successful inoculation and incubation result in infection.

As a particular pathogen grows in a host plant, symptoms begin to appear. Before symptoms develop, many biochemical and physiological

changes have usually occurred. Visible symptoms are responses of the plant to disease processes that have been occurring since inoculation.

Some diseases, including many of the root rots, have only one cycle during a growing season. Other diseases, especially ones that occur in aerial parts of the host, develop secondary or repeating disease cycles during a growing season. Recurrent crops of spores or bacterial cells, maturing every seven to 14 days, provide inoculum to infect nearby healthy tissue and plants. Such diseases develop quickly and may cause severe damage over a short period of time (epidemic).

The disease cycle is completed when a pathogen reaches the survival stage. Many pathogens produce specialized structures such as sclerotia and resistant spores that enable the pathogen to resist freezing, drying, or other adverse conditions until the disease cycle can be completed once again.

PLANT DISEASE MANAGEMENT

Plant diseases are most often controlled with cultural techniques that include practices such as planting date, planting sites, irrigation management, crop rotation and proper agronomic practices. The most effective and economical way to control diseases is through the use of resistant cultivars. Plant diseases are generally managed using a preventive strategy rather than implementing control after the disease is present. Most plant disease control chemicals are not effective in eradicating existing disease and must be used before the disease is present. For these reasons only a small number of pesticides are used to control plant disease under normal conditions.

Epidemiology enables plant protection specialists to study pathogens and identify effective methods of controlling or managing them and their potential to cause losses due to disease. Control methods are classified as **regulatory, cultural, biological, physical,** and **chemical.**

Regulatory controls try to exclude a pathogen from a host or from a certain geographic area. Most cultural controls help plants avoid contact with a pathogen and eradicate or reduce the amount of a pathogen (inoculum) in a plant, field, or area. Biological and some cultural controls improve host resistance or favor microorganisms antagonistic to the pathogen.

Physical and chemical controls protect plants from pathogen inoculum that may arrive and cure or reduce infection that is already in progress. Individual control methods are usually integrated to provide a more comprehensive and effective strategies for management of a disease, a disease complex, and multiple pests that often threaten an individual crop during its development.

Eradication and reduction of pathogen inoculum can be achieved by regulatory controls such as quarantines and inspections. Disease-resistant varieties and pathogen-free seed and propagating material are important and effective tools. Host eradication, crop rotation, sanitation, planting date, improving plant growing conditions, creating conditions unfavorable to pathogens, mulching, irrigation method and timing, and cultivation methods represent cultural practices that can be altered to more effectively manage many plant pathogens.

Some physical methods such as soil sterilization, heat treatment, refrigeration, and radiation, chemical methods such as soil fumigation and seed treatment, and biological methods such as antagonistic organisms and trap crops can also reduce inoculum and the potential for disease epidemics to occur.

Direct protection against pathogen infection and development is achieved using chemical compounds that are toxic to the pathogen. Such chemicals limit growth and multiplication, inhibit pathogen germination, or are lethal to the pathogen. Some chemicals are toxic to all or most kinds of pathogens, while others only affect one or a few pathogens. Depending on the kind of pathogens they affect, the chemicals are called fungicides, bactericides, nematicides, or herbicides. Insecticides are used to control the insect vectors of some pathogens.

Some of the newer fungicides, such as sterile inhibitors, have a therapeutic (eradicant) action, and several are absorbed and systemically translocated by the plant (systemic). Fungicides may be applied to the soil (fumigation, soil furrow treatments), seed, irrigation system, foliage, and other plant parts (dust, liquid treatments).

Soil fumigants and treatments reduce the amount of initial inoculum present before planting a crop susceptible to a slow-moving disease such as root rot or even nematodes. Fumigants must be applied to well-cultivated soil with low organic matter, in the presence of adequate moisture, and while temperatures are above 50 degrees F. Treated sites must remain fallow for several days to weeks so that the fumigant volatilizes completely and is no longer toxic to seed and seedlings.

Seed treatments protect seedlings against infection by soil-borne pathogens during the first few days of germination and emergence. Most of these chemicals act only at the surfaces of seed and in the nearby soil. However, some chemicals may penetrate to eradicate pathogens within the seed and seedling.

Foliar treatments provide a protective layer against and exclude pathogens (protectants) or eradicate (systemics) pathogens from treated plant parts. Correct timing, thorough application, and choice of the proper chemical are essential for effective and economical control. Because many fungicides and bactericides are protectant in their action, it is important that they be on the plant surface before the pathogen arrives or germinates, enters the host, and establishes itself. Since many pesticides are effective only on contact with the pathogen, and pathogens are not generally mobile, it is important that the whole surface of the plant be covered with the chemical.

Fungicides and Bactericides Used In Utah

1. Antibiotics (streptomycin, tetracycline)
2. Coppers (cupric hydroxide, copper oxychloride, copper ammonium carbonate)
3. Inorganic and organic sulfurs
4. Dithiocarbamates (thiram, maneb, mancozeb, metam-sodium)
5. Aromatics (pentachloronitrobenzene, dichloran, chlorothalonil)
6. Heterocyclic compounds (captan, captafol, iprodione, vinclozolin)
7. Acylalanine (metalaxyl)
8. Benzyimidazoles (benomyl, thiabendazole)
9. Oxathiin (carboxin)
10. Organic phosphate (fosetyl-Al)
11. Pyrimidine (fenarimol)
12. Triazoles (myclobutanil, triadimefon, propiconazole)
13. Other systemics (chloroneb, ethazol, imazalil, thiophanate-methyl)

Nematicides Used In Utah:

1. Halogenated hydrocarbons (methyl bromide)
2. Organophosphates (disulfoton, fenamiphos)
3. Isothiocyanates (vorlex)
4. Carbamates (aldicarb, carbofuran, oxamyl)
5. Chloropicrin

A list of major plant diseases in Utah appears in Appendix 3.

IV. WORKER PROTECTION STANDARD

The U.S. Environmental Protection Agency's Worker Protection Standard (WPS), as revised in 1992, must be complied with when pesticides are used on agricultural establishments, including farms, forests, nurseries, and greenhouses, for the commercial or research production of agricultural plants. The WPS requires employers to provide agricultural workers and pesticide handlers with protections against possible harm from pesticides. Persons who must comply with these instructions include owners or operators of agricultural establishments and owners or operators of commercial businesses that are hired to apply pesticides on the agricultural establishment or to perform crop-advising tasks on such establishments. Family members who work on an agricultural or commercial pesticide establishment are considered employees in some situations.

WPS requirements for employers include:

- **Displaying information** about pesticide safety, emergency procedures, and recent pesticide applications on agricultural sites.
- **Training** workers and handlers about pesticide safety.
- Helping employees get **medical assistance** in case of a pesticide related emergency.
- Providing **decontamination sites** to wash pesticide residues off hands and body.
- Compliance with **restricted entry intervals** (REI)– the time after a pesticide application when workers may not enter the area.
- **Notifying** workers through posted and/or oral warnings about areas where pesticide applications are taking place and areas where REI are in effect.
- Allowing only **trained and equipped workers** to be present during a pesticide application.
- Providing **personal protective equipment** (PPE) for pesticide handlers and also for workers who enter pesticide treated areas before expiration of the REI.
- **Protecting pesticide handlers** by giving them safety instructions about the correct use of pesticide application equipment and PPE and monitoring workers and handlers in hazardous situations.

One of the provisions of the WPS is the requirement that employers provide handlers and workers with ample water, soap, and single use towels for washing and decontamination from pesticides and that emergency transportation be made available in the event of a pesticide poisoning or injury. The WPS also establishes REI and the requirements for PPE. PPE requirements are specified for all pesticides used on farms and in forests, greenhouses, and nurseries. Some pesticide products already carried REI and PPE directions. This rule raised the level of protection and requirements for all pesticide products.

Other major provisions require that employers inform workers and handlers about pesticide hazards through safety training. Handlers must have easy access to pesticide label safety information and a listing of treatments site must be centrally located at the agricultural facility. Handlers are prohibited from applying a pesticide in a way that could expose workers or other people.

V. PROTECTING GROUNDWATER AND ENDANGERED SPECIES

INTRODUCTION

Federal and state efforts to protect groundwater and endangered species have resulted in special requirements and restrictions for pesticide handlers and applicators. Pesticides that are incorrectly or accidentally released into the environment can pose a threat to groundwater and endangered species. Whether pesticides are applied indoors or outdoors, in an urban area or in a rural area, the endangered species and groundwater must be protected and state and federal agencies rigidly enforce this requirement.

The need for special action by the pesticide handler/applicator depends on site location. Groundwater contamination is of special concern in release sites where groundwater is close to the surface or where the soil type or the geology allows contaminants to reach groundwater easily. In the case of endangered species, special action is normally required in locations where the species currently live or in locations where species are being reintroduced. The product labeling is the best source to determine if pesticide use is subject to groundwater or endangered species limitations.

The U.S. Environmental Protection Agency (EPA) establishes the specific limitations or instructions for pesticide users in locations where groundwater or endangered species are most at risk. These limitations and instructions may be too detailed for inclusion in pesticide labeling. In such cases the labeling will direct the applicator or handler to another source for instructions and restrictions. The legal responsibility for following instructions that are distributed separately is the same as it is for instructions that appear on the pesticide labeling.

PROTECTING GROUNDWATER

Groundwater is water located beneath the earth's surface. Many people think that groundwater occurs in vast underground lakes, rivers, or streams. Usually, however, it is located in rock and soil. It moves very slowly through irregular spaces within otherwise solid rock or seeps between particles of sand, clay, and gravel. An exception is in limestone areas, where groundwater may flow through large underground channels or caverns. Surface water may move several feet in a second or a minute. Groundwater may move only a few feet in a month or a year. If the groundwater is capable of providing significant quantities of water to a well or spring, it is called an aquifer. Pesticide contamination of aquifers is very troubling, because these are sources of drinking, washing, and irrigation water.

Utah has implemented a comprehensive and coordinated approach to protect groundwater from pesticide contamination. Formulation of the Utah Groundwater and Pesticide State Management Plan is a cooperative effort between federal, state, private agencies, producers, and user groups. It provides a basis for continuing future efforts to protect groundwater from contamination whenever possible. Furthermore, this plan provides agencies with direction for management policies, regulations, enforcement, and implementation of groundwater strategies.

Utah recognizes that the responsible and wise use of pesticides can have a positive economic impact, yield a higher quality of life, enhance outdoor activities, and give relief from annoying pests. The EPA has authorized the Utah Department of Agriculture and Food (UDAF) to enforce the protection of groundwater from pesticides.

The UDAF, in concert with cooperating agencies and entities, demands strict compliance with all pesticide labels, handling procedures, and usage to protect groundwater in the state.

Prevention of groundwater contamination is important, because once the water is polluted, it is very difficult and costly to correct the damage and in some instances impossible. City and urban areas contribute to pollution because water runoff can contain pesticides. Shallow aquifers or water tables are more susceptible to contamination than deeper aquifers or water tables. Sandy soils allow more pollution to move than clay or organic soils, because clays and organic matter adsorb many of the contaminants. For more information about what groundwater is and where it comes from, read the study manual ***Applying Pesticides Correctly: A Guide for Private and Commercial Applicators.***

The Federal Insecticide, Fungicide and Rodenticide Act (FIFRA), as amended, establishes a policy for determining the acceptability of a pesticide use or the continuation of that use, according to a risk/benefit assessment. As long as benefits outweigh adverse effects, the EPA can continue to register the pesticide. Although the intent of a pesticide application is to apply the pesticide to the target or pest, part of the pesticide will fall on the area around the target or pest. Rain or irrigation water then can pick up the part that is not degraded or broken down and carry it to the groundwater via leaching.

There are many factors that influence the amount of pesticide contamination that can get into groundwater. The major factors are the soil type, soil moisture, persistence in soil, placement of the pesticide, frequency of application, pesticide concentration and formulation, pesticide water solubility, and precipitation. Each of these factors will influence the amount of pesticide that can penetrate the soil surface, leave the root zone, and percolate into groundwater.

Although some pesticides may have a high adsorption quality, when they are applied to sandy soil, they may still migrate to the water table because there are few clay particles or little organic matter to bind them. The management and use of pesticides is up to the individual applicator and/or landowner as to whether safe practices are used. Groundwater is a very valuable resource and it must be protected from pesticide contamination.

PROTECTING ENDANGERED SPECIES

The Federal Endangered Species Act lists the three classifications as endangered, threatened, and experimental. Endangered has the highest level of protection. The phrase "endangered species" is used when referring to these classifications. This Act was passed by Congress to protect certain plants and wildlife that are in danger of becoming extinct. A portion of this Act requires EPA to ensure that these species are protected from pesticides.

EPA's goal is to remove or reduce the threat to endangered species that pesticides pose. Achieving this goal is a portion of the larger continuing effort to protect species at risk. Normally these restrictions apply to the habitat or range currently occupied by the species at risk. Occasionally the restrictions apply where endangered species are being reintroduced into a habitat previously occupied.

Habitats are the areas of land, water, and air space that an endangered species needs for survival. Such areas include breeding sites, sources of food, cover, and shelter, and the surrounding territory that provides space for normal population growth and behavior.

Utah's endangered species plan is a cooperative effort between federal, state, private agencies, producers, and user groups. This plan provides agency direction for regulations, enforcement, management policies, and implementation of threatened and endangered species protection strategies.

EPA launched a major project known as Endangered Species Labeling (ESL). The goal is to remove or reduce the threat to endangered species from pesticides. EPA has the responsibility to protect wildlife and the environment against hazards posed by pesticides. The ESL program is administered by the U.S. Fish and Wildlife Service (FWS) in the U.S. Department of Interior. The FWS reports to EPA concerning endangered species. EPA and FWS work cooperatively to ensure that there is consistency in the pesticide restriction information provided to agencies and pesticide users.

The UDAF acts under the direction and authority of EPA to carry out the ESL project as it relates to the use of pesticides in Utah. Utah's web sites with maps designating the habitat boundaries and listings of endangered plants and wildlife is: www.utahcdc.usu.edu

VI. CALIBRATION INFORMATION

Unit Conversion

One acre = 43,560 square feet	Example: ½ acre = 21,780 square feet
One mile = 5,280 feet	Example: ¼ mile = 1320 feet
One gallon = 128 fluid ounces	Example: ½ gallon = 64 fluid ounces
One quart = 2 pints = 4 cups = 32 fluid ounces	Example: 2 quarts = 64 fluid ounces
One pint = 2 cups = 16 fluid ounces	Example: ½ pint = 1 cup = 8 fluid ounces
One tablespoon = 3 teaspoons = 0.5 fluid ounces	Example: 2 tablespoons = 1 fluid ounce
One pound = 16 ounces	Example: ¼ pound = 4 ounces
One gallon = 231 cubic inches	Example: 2 gallons = 462 cubic inches

Weights

1 ounce	= 28.35 grams
16 ounces	= 1 pound = 453.59 grams
1 gallon water	= 8.34 pounds = 3.785 liters = 3.78 kilograms

Liquid Measures

1 fluid ounce	= 2 tablespoons = 29.573 milliliters
16 fluid ounces	= 1 pint = 0.473 liters
2 pints	= 1 quart = 0.946 liters
8 pints	= 4 quarts = 1 gallon = 3.785 liters

Length

1 foot	= 30.48 centimeters
3 feet	= 1 yard = 0.9144 meters
16 1/2 feet	= 1 rod = 5.029 meters
5280 feet	= 320 rods = 1 mile = 1.6 kilometers

Area

1 square foot	= 929.03 square centimeters
9 square feet	= 1 square yard = 0.836 square meters
43560 square feet	= 160 square rods = 1 acre = 0.405 hectares

Speed

1.466 feet per second = 88 feet per minute = 1 mph = 1.6 kilometers per hour (kph)

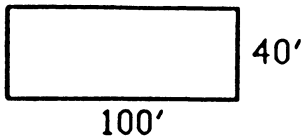
Volume

27 cubic feet = 1 cubic yard = 0.765 cubic meters 1 cubic foot = 7.5 gallons = 28.317 cubic decimeters

Area and Volume Calculations:

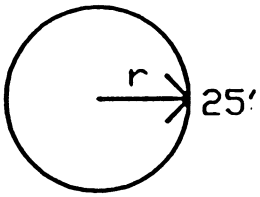
Area of Rectangular or Square Shape

The area of a rectangle is found by multiplying the length (L) times the width (W).
(Length) x (Width) = Area
Example: (100 feet) x (40 feet) = 4000 square feet



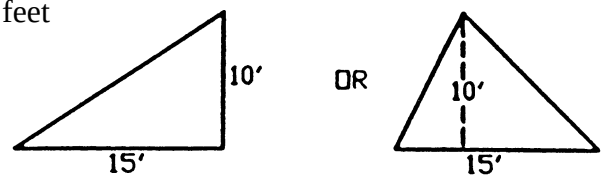
Area of Circle

The area of a circle is the radius (radius = one-half the diameter), times the radius, times 3.14.
(radius) x (radius) x (3.14) = Area
Example: (25 feet) x (25 feet) x (3.14) = 1962.5 square feet



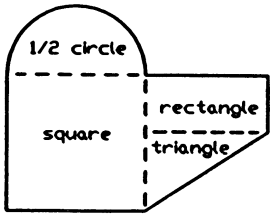
Area of Triangular Shape

To find the area of a triangle, multiply ½ times the width of the triangle's base, times the height of the triangle.
(½) x (base width) x (height) = Area
Example: (½) x (15 feet) x (10 feet) = 75 square feet

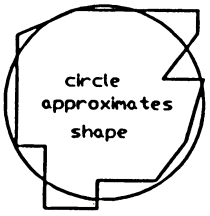


Area of Irregularly Shape

Irregularly shaped sites can often be reduced to a combination of rectangles, circles, and triangles. Calculate the area of each shape and add the values together to obtain the total area.
Example: Calculate the area of the rectangle, triangle, square, and one-half of a circle.



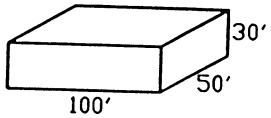
Another method is to convert the site into a circle. From a center point, measure the distance to the edge of the area in 10 or more increments. Average these measurements to find the radius, then calculate the area using the formula for a circle.
Example: Approximate the area by calculating the area of a similarly sized circle.



Volume of Cube and Box Shapes

The volume of a cube or box is found by multiplying the length, times the width, times the height.
(Length) x (Width) x (Height) = Volume

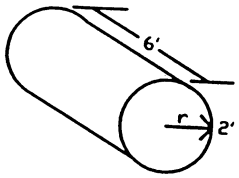
Example: (100 feet) x (50 feet) x (30 feet) = 150,000 cubic feet



Volume of Cylindrical Shapes

The volume of a cylinder is found by calculating the area of the round end (see formula for circle) and multiplying this area times the length or height.

Example: (radius) x (radius) x (3.14) = Area of Circle
(Area of Circle) x (Length) = Volume of Cylinder
(2 feet) x (2 feet) x (3.14) x (6 feet) = 75.36 cubic feet



Sprayer Calibration Formulas

To Calculate Travel Speed in Miles Per Hour:
The travel speed of a sprayer is determined by measuring the time (seconds) required to travel a know distance (such as 200 feet). Insert the values in the following formula to determine the miles per hour.

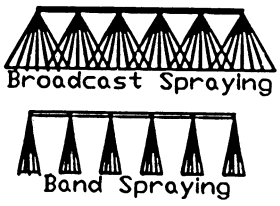
$$\frac{\text{Distance in Feet x 60}}{\text{Time in Seconds x 88}} = \text{Miles Per Hour}$$

Example: $\frac{\text{(200 feet) x (60)}}{\text{(30 seconds) x (88)}} = \frac{12{,}000}{2640} = 4.55 \text{ mph}$

To Calculate the Gallons Per Minute Applied During Broadcast Spraying:
The application rate in gallons per minute (GPM) for each nozzle is calculated by multiplying the gallons per acre (GPA), times the miles per hour (MPH), times the nozzle spacing in inches (W); then dividing the answer by 5940. For small adjustments in GPM sprayed, operating pressure is changed. For large adjustments in GPM sprayed, travel speed (miles per hour) is changed or nozzle size is changed.

$$\frac{\text{GPA x MPH x W}}{5940} = \text{GPM}$$

Example: $\frac{\text{(12 GPA) x (4.5 MPH) x (24")}}{5940} = \frac{1296}{5940} = 0.22 \text{ GPM}$



To Calculate the Gallons Per Minute Applied During Band Spraying:
Broadcast spraying applies chemicals to the entire area. Band spraying reduces the amount of area and chemicals sprayed per acre. To use the above formulas for band sprayer applications, use the band width (measured in inches) rather than nozzle spacing for the "W" value.

Pesticide Mixing

Terminology:

The ***active ingredients*** of a pesticide are the chemicals in a formulation that control the target pests. The ***formulation*** is the pesticide product as sold, usually a mixture of concentrated active ingredients and an inert material. Restricted use pesticides are purchased in formulations requiring ***dilution prior to application***. Formulations are diluted with inert substances such as water. The ***percentage of active ingredients*** in a pesticide formulation directly affects dilution and application rates. Given two pesticides, A = 50% active ingredients, B = 100% active ingredients; twice as much pesticide A formulation is required to equal pesticide B formulation.

To Determine Total Amount of Pesticide Formulation Required Per Tank:

To calculate the total amount of pesticide formulation needed per spray tank, multiply the recommended dilution, ounces/pints/cups/teaspoons/tablespoons/etc. of pesticide per gallon of liquid, times the total number of gallons to be mixed in the sprayer. A full or partial tank of pesticide spray may be mixed.

(Dilution Per Gallon) x (Number of Gallons Mixed) = Required Amount of Pesticide Formulation

Example: (3 ounces per gallon) x (75 gallons) = 225 ounces

Note: 1 gallon = 128 ounces; through unit conversion 225 ounces = 1.76 gallons

To Calculate the Amount of Pesticide Formulation Sprayed Per Acre:

The amount of pesticide formulation sprayed per acre is determined by multiplying the quantity of formulation (ounces/pounds/pints/cups/teaspoons/tablespoons/etc.) mixed per gallon of water, times the number of gallons sprayed per acre.

(Quantity of Formulation Per Gallon) x (Gallons Sprayed Per Acre) = Formulation Sprayed Per Acre

Example: (1/2 pound per gallon) x (12 gallons per acre) = 6 pounds per acre

Amount of Active Ingredients Sprayed Per Acre:

To calculate the amount of active ingredients (AI) applied per acre, multiply the amount (pounds, gallons, ounces, etc) of pesticide formulation required per acre, times the percentage of active ingredients in the formulation (100%, 75%, 50%, 25%, etc.), and divide the value by 100.

$$\frac{\text{(Amount of Formulation Required Per Acre) x (Percentage of AI)}}{100} = \text{Active Ingredients Per Acre}$$

Example: $\frac{\text{(4 pounds formulation sprayed per acre) x (75\% AI)}}{100}$ = 3 pounds of AI sprayed per acre

Note: 75 % = 0.75

To Calculate the Gallons of Pesticide Mixture Sprayed Per Acre:

The amount of pesticide mixture sprayed per acre is determined by dividing the number of gallons sprayed by the number of acres sprayed.

$$\frac{\text{Gallons Sprayed}}{\text{Acres Sprayed}} = \text{Gallons Sprayed Per Acre}$$

Example: $\frac{\text{200 Gallons Sprayed}}{\text{10 Acres Sprayed}}$ = 20 gallons of pesticide mixture sprayed per acre

APPENDICES

	Page
Appendix 1. Utah Major Insect Pests by Crop	35
Appendix 2. Utah Noxious and Restricted Weeds and Seeds	38
Appendix 3. Utah Major Plant Diseases by Crop	39

Appendix 1. Utah Major Insect Pests by Crop

The following lists include insects and other arthropods.

Field Crop Insects

Alfalfa

Alfalfa caterpillar
Alfalfa weevil (majority of insect pest damage in Utah alfalfa caused by this insect.)
Army cutworm
Blue aphid
Pea aphid
Spotted alfalfa aphid
Variegated cutworm
Grasshoppers (Utah's 10 primary species)

- Big-headed Grasshopper
- Clear-winged or Warrior Grasshopper
- Differential Grasshopper *
- Lubber Grasshopper
- Migratory Grasshopper *
- "P. quad" Grasshopper
- Packard Grasshopper *
- Red-legged Grasshopper *
- Two-striped Grasshopper *
- White-whiskers Grasshopper

(* Ninety percent of the grasshopper damage in Utah is caused by these five grasshoppers.)

Small Grains

Army Gutworm
Army Worm
Banks Grass Gite
Brown Wheat Mite
Cereal Leaf Beetle
False Wireworm
Flea Beetle
Grasshopper
Greenbug
Hessian Fly
Russian Wheat Aphid
Wheat-stem Maggot
White Grub

Corn and Sorghum

Corn Earworm
Corn Flea Beetle
Corn-leaf Aphid
Corn Rootworm
Cutworms
European Corn Borer
Red Spider Mite
Sorghum Greenbug

Dry Bean

Bean-leaf beetle
Mexican bean beetle
Western bean cutworm

Fruit Tree Insects

Apple

Campylomma Bug
Codling moth
Cutworm
European Red Mite
Leafroller (obliquebanded, fruit tree, Pandemis)
Lygus Bug
Green Apple Aphid
Rosy Apple Aphid
San Jose Scale
Spider mite (Two-spotted and McDaniel)
Stink bug
Fruitworm (green, pyramidal, others)
Western Flower Thrip
Western Tentiform Leafminer
White Apple Leafhopper
Woolly Apple Aphid

Apricot

European Red Mite
Green Peach Aphid
Lygus Bug
Oriental Fruit Moth
Peach Silver Mite
Peach Twig Borer
Peachtree (Crown) Borer
San Jose Scale
Spider Mite (Twospotted and McDaniel)
Stink Bug

Cherry

Black Cherry Aphid
Cherry/pear slug
Cutworm
European Red Mite
Leafroller
Prunus rust mite
San Jose Scale
Shothole Borer
Spider Mite (Twospotted and McDaniel)
Western Cherry Fruit Fly

Peach/Nectarine

Box Elder Bug
Cutworm
European Red Mite
Green Peach Aphid
Lygus Bug
Peach Silver Mite
Peach Twig Borer
Peachtree (Crown) Borer
San Jose scale
Spider Mite (Twospotted and McDaniel)
Stink Bug
Oriental Fruit Moth
Western Flower Thrip

Pear

European Red Mite
Codling Moth
Cutworm
Leafroller
Lygus Bug
Pear/Cherry Slug
Pear leaf blister mite
Pear Psylla
Pear Rust Mite
San Jose Scale
Spider mite (Twospotted and McDaniel)
Stink Bug

Vegetable Insects

Soil
Flea beetle
Root weevil
White grub
Wireworm

Piercing-Sucking
Aphid (many species)
Leafhopper (many species)
Spider mite
Stink bug
Squash bug
Thrip
Whitefly

Non-insect chewing pests:
Sowbug, snail, and slug

Chewing
Armyworm
Cabbage Looper
Click beetle
Wireworm
Corn earworm
Tomato Fruitworm
Corn rootworm
Colorado potato beetle
Cutworm
Diamond-back moth
European earwig
Flea beetle
Grasshopper
Imported cabbage worm
Mexican bean beetle
Root weevil
Striped and spotted cucumber beetle
Tomato hornworm

Rangeland Insects

Black grass bug
Grasshopper (See list under alfalfa insects.)
The majority of grasshopper crop damage is the result of grasshopper migrations from rangeland to cropland.
Mormon cricket

Beneficial Arthropods

Ambush Bug
Big-eyed Bug
Damsel Bug
Ground Beetle
Hover fly (Syrphidae)
Lacewing
Lady beetle (Coccinellidae)
Minute Pirate Bug
Parasitic Wasp
Praying Mantis
Predaceous Midge
Predaceous mite (Phytoseiidae)
Spider

Appendix 2. Utah Noxious Weeds, Restricted Weeds and Seeds

Utah Noxious Weed Act R68-8 lists the following noxious weeds:

Bermudagrass	(*Cynodon dactylon variety dactylon*) Bermudagrass is not a noxious weed in Washington County
Bindweed (Wild morning glory)	(*Convolvulus, species plural*)
Broadleaved peppergrass (Tall Whitetop)	(*Lepidium latifolium*)
Canada thistle	(*Cirsium arvense*)
Diffuse knapweed	(*Centaurea diffusa*)
Dyers Woad	(*Isatis tinctoria*)
Leafy Spurge	(*Euphorbia esula*)
Medusahead	(*Taeniatherum caput-medusae subspecies caput-medusae*)
Musk thistle	(*Carduus nutans*)
Perennial sorghum, species plural	(*Sorghum halepense*) and (*Sorghum almum*) Including but not limited to Johnson grass
Purple loosestrife	*(Lythrum Salicaria)*
Quackgrass	(*Elytrigia repens*)
Russian Knapweed	(*Acroptilon repens*)
Scotch Thistle (Cotton thistle)	(*Onopordum acanthium*)
Spotted knapweed	(*Centaurea maculosa*)
Squarrose Knapweed	(*Centaurea virgata subspecies squarrosa*)
Whitetop	(*Cardaria, species plural*)
Yellow starthistle	(*Centaurea solsitialis*)

Utah Seed Law R68-8 lists the following prohibited noxious weed seeds

Bermudagrass	(*Cynodon dactylon variety dactylon*) Bermudagrass is not a noxious weed in Washington County
Bindweed (Wild morning glory)	(*Convolvulus, species plural*)
Broadleaved peppergrass (Tall whitetop)	(*Lepidium latifolium*)
Canada thistle	(*Cirsium arvense*)
Diffuse knapweed	(*Centaurea maculosa*)
Dyers woad	(*Isatis tinctoria*)
Leafy spurge	(*Euphorbia esula*)
Medusahead	(*Taeniatherum caput-medusae subspecies caput-medusae*)
Musk thistle	(*Carduus nutans*)
Perennial sorghum, species plural	(*Sorghum halepense*) and (*Sorghum almum*) Including but not limited to Johnson grass
Purple loosestrife	*(Lythrum Salicaria)*
Quackgrass	(*Elytrigia repens*)
Russian knapweed	(*Acroptilon repens*)
Scotch thistle (Cotton thistle)	*(Onopordum acanthium*)
Spotted knapweed	*(Centaurea maculosa*)
Squarrose knapweed	*(Centaurea virgata subspecies squarrosa*)
Whitetop	(*Cardaria, species plural*)
Yellow starthistle	(*Centaurea solsitialis*)

Utah Seed Law R68-8 lists the following restricted weed seeds :

Dodder	(*Cuscuta spp*.)
Halogeton	(*Halogeton glomeratus*)
Jointed goatgrass	(*Aegilops cylindrica*)
Poverty weed	(*Iva axillaris*)
Wild oats	(*Avena fatua*)

Appendix 3. Utah Major Plant Diseases By Crop

Alfalfa

Common and head smut
Root and crown rot
Stem nematode
Verticillium (most serious alfalfa disease)

Small Grains

Barley yellow dwarf virus
Bunt

Root and foot rot

Smuts

Tan spot

Corn and Sorghum

Fusarium stalk rot

Head smut

Dry Bean

Bacterial diseases: halo blight, bacterial brown spot, and common bacterial blight
Rust
White mold

Potato

Blackleg
Early blight

Cole Crops (like cabbage) and Lettuce

Blackleg
Black rot
Bottom rot

Fruit Tree

Bacterial blast
Coryneum blight
Cytospora canker
Fire blight
Pear decline
Phytophthora root rot
Powdery mildew
Stem pitting virus

Sugar Beets

Cercospora leaf blight

Powdery mildew

Sugar beet nematode

Pepper

Mosaic virus
Phytophthora wilt

Spinach

Downy mildew
Rusts

Cucurbit

Angular leaf spot
Bacterial wilt
Cucumber mosaic virus

Onion

Botrytis neck rot
Fusarium basal rot
Pinkroot

Tomato

Early blight
Fusarium wilt
Spotted wilt virus

GLOSSARY OF TERMS

A

ABSORPTION - The process by which pesticides are taken into plants by roots or foliage (stomata, cuticle, etc.).
ADJUVANT - Material added to a pesticide mixture to improve or alter the deposition, toxic effects, mixing ability, persistence, or other qualities of the active ingredient.
ADSORPTION - The adhesion of pesticide spray droplets to the plant's surface.
ANNUAL - A plant that completes its life cycle within one year, then dies.
ANTIBIOTIC - Chemical substance produced by one micro-organism that inhibits or kills other micro-organisms.
AQUIFER - Underground formation of sand, gravel, or porous rock that contains water; the place where groundwater is found.
AROMATICS - Compounds derived from the hydrocarbon benzene (C_6H_6).

B

BACTERICIDE - Pesticide that inhibits or kills bacteria or prevents their growth.
BACTERIUM - Single-celled microscopic plant that lacks chlorophyll.
BAND APPLICATION - An application of spray or dust to a continuous restricted area such as in or along a crop row rather than over the entire field.
BASAL TREATMENT - Applied to encircle the stem of a plant above and at the ground such that foliage contact is minimal. A term used mostly to describe treatment of woody plants.
BIENNIAL - Plant that completes its growth in two years. The first year, it produces leaves and stores food; the second year, it produces fruits and seeds.
BIOLOGICAL CONTROL - control of pests by means of predators, parasites, disease-producing organisms, competitive microorganisms, or decomposing plant material which reduce the population of the pathogen.
BLIGHT - Disease characterized by general and rapid killing of leaves, flowers and stems.
BLOTCH - Disease characterized by large, irregular spots or blots on leaves, shoots, stems and fruits.
BROADCAST TREATMENT - Application of a pesticide over an entire field area.

C

CANKER - Necrotic, often sunken lesion on a stem, branch or twig.
CARRIER - The liquid or solid material added to an active ingredient to facilitate its storage, shipment, or use in the field.
CHLOROSIS - Yellowing of normally green tissue due to chlorophyll destruction or failure of chlorophyll formation.
COMPATIBLE - Quality of two compounds that permits them to be mixed without effect on the properties of either.
CONCENTRATION - The amount of active material in a given volume of diluent.
CONTACT HERBICIDE - Herbicide that causes localized injury to plant tissue when contact occurs.
CORTEX - All tissues outside the xylem of a plant stem or root.
COTYLEDON - The first leaf or leaves of a growing plant embryo.
COTYLEDON LEAVES - The first leaf or pair of leaves of the embryo of seed plants.
CROWN - The point where stem and root join in a seed plant.
CUTICLE - The outer protective covering of plants which aids in preventing water loss.

D

DAMPING-OFF - Destruction of seedlings near the soil line resulting in wilt and death.
DEGRADATION - The breakdown of a pesticide into an inactive or less active form. Environmental conditions, microorganisms, or other chemicals can contribute to the degradation of pesticides.
DIEBACK - Progressive death of shoots, branches and roots generally starting at the tip.
DIRECTED APPLICATION - Precise application to a specific area or plant organ such as to a row or bed or to the leaves or stems of plants.
DISEASE - Any malfunctioning of host cells and tissue that results from continuous irritation by a pathogenic agent or environmental factor and that leads to the development of symptoms.
DORMANCY - State of inhibited germination of seeds or growth of plant organs. A state of suspended development.

E

EFFICACY - The ability of a pesticide to produce a desired effect on a target organism.
EMERGENCE - Appearance of the first part of the crop plant above the ground.
EMULSIFYING AGENT - Material which facilitates the suspending of one liquid in another.
EMULSION - Mixture in which one liquid is suspended in tiny globules in another liquid; for example, oil in water.
ENATION - Raised, corrugated outgrowths chiefly of a biotic disease.
ERADICATION - Pest management strategy that attempts to eliminate all members of a pest species.
ETIOLATION - Elongation and yellowing or blanching of a green plant through lack of sunlight. Stem internodes may be elongated.
EXUDATE - Substance, usually liquid, discharged from a plant or animal through a natural opening or from diseased tissue through a wound.

F

FALLOW - Cultivated land that is allowed to lie dormant during a growing season.
FOLIAR APPLICATION - Pesticide application to plant leaves or foliage.
FORMULATION - Pesticide prepared by the manufacturer requiring dilution prior to application.
FRUITING BODY - Complex fungus structure that contains spores. Characteristic types aid in fungus identification.
FUMIGANT - Gaseous or readily volatilized pesticide.
FUNGICIDE - Pesticide used to control, suppress, or kill plant disease agents or severely interrupt their normal growth.
FUNGUS - Organism with no chlorophyll that reproduces by sexual or asexual spores usually with mycelium.

G

GALL - Swelling or overgrowth produced on a plant as a result of infection by certain pathogens.
GERMINATION - The beginning process when a plant sprouts from a seed.
GRANULAR - Dry formulation of pesticide and other components in discrete particles generally less than ten cubic millimeters in size.
GROWTH STAGES - (1) tillering stage: when a plant produces additional shoots from a single crown, as in wheat. (2) jointing stage: when the internodes of the stem are elongating. (3) boot stage: when the seedhead of a plant begins to emerge from the sheath (usually grain crops).

H

HERBICIDE - Pesticide used to control, suppress or kill plants or severely interrupt their normal growth processes.

HOST - Plant or animal that is invaded by a parasite and from which the parasite gets its nutrients.

HYPHA - Single branch of a fungus mycelium.

I

IMPERFECT STAGE - Part of the life cycle of a fungus in which no sexual spores are produced.

INCUBATION PERIOD - Period of time between penetration of a host by a pathogen and the first
appearance of symptoms on the host.

INFECTION - Establishment of a pathogen within a host.

INHIBIT - To prevent something from happening, such as a biological reaction within the tissues of a plant or animal.

INOCULUM - Infectious pathogen or its spores, mycelium, or virus, bacteria or mycoplasma particles that are capable of infecting plants or animals.

INSECTICIDE - Chemical used to control, suppress or kill insects or severely interrupt their normal growth processes.

L

LEACHING - Process by which some pesticides move down through the soil, usually by being dissolved in water, with the possibility of reaching groundwater.

LESION - Localized area of discolored, diseased tissue.

M

MERISTEMATIC TISSUE - Plant tissue that is in the process of actively growing and dividing, such as those at the apex of growing stems and roots.

MILDEW - Fungal disease in which the mycelium and spores are seen as a whitish growth on the host surface.

MODE OF ACTION - The way a pesticide reacts with a pest organism to destroy it.

MOLD - Any profuse or woolly fungus growth on damp or decaying matter or on surfaces of host tissue.

MOSAIC - Variegated pattern of greenish and yellowish shades in leaves usually caused by a disruption of the chlorophyll content.

MOTTLE - Irregular pattern of indistinct light and dark areas.

MYCELIUM - Mass of interwoven threads (hyphae) that make up the vegetative body of a fungus.

N

NECROSIS - Death of plant cells usually resulting in the affected tissue turning brown or black.

NEMATICIDE - Pesticide that inhibits or kills nematodes.

NEMATODE - Non-segmented, microscopic round worm usually threadlike and free-living or parasitic on plants.

NON-SELECTIVE HERBICIDE - Herbicide that is generally toxic to plants, without regard to species. Toxicity may be a function of dosage, method of application, etc.

NOXIOUS - Something that is harmful to living organisms, such as noxious weeds.

O

OBLIGATE PARASITE - Parasite that in nature can grow and multiply only on or in living organisms.

P

PARASITE - An organism that lives on or in a living host and that gets all or part of its nutrients from the host.

PARTICLE DRIFT - Spray particles which are carried away from the

application area by air movements at the time of or soon after application.
PATHOGEN - Any organism capable of causing disease. Most pathogens are parasites.
PERFECT STAGE - Period of life during which a fungus produces sexual spores.
PELLET - Dry formulation of pesticide and other components in discrete particles, usually larger than ten cubic millimeters.
PERENNIAL - Plant that lives from year to year, but for three years or more under normal growing conditions.
PERSISTENT HERBICIDE - Herbicide which will harm crops planted in rotation after harvesting the treated crop, or which interferes with re-growth of native vegetation in non-crop sites for an extended period of time. (See residual herbicide.)
pH - Measure of a solution's acidity or alkalinity; 7 is numerically equal to a neutral solution, pH increases with increasing alkalinity, while pH decreases with increasing acidity.
PHOTOSYNTHESIS - Process by which plants convert sunlight into energy.
PHYTOPLASMAS - Forms of life intermediate between viruses and bacteria. They lack an organized nucleus and cell wall and are transmitted by leafhoppers.
PHYTOTOXIC - Injurious to plants. Excesses of pesticides and fertilizers can be phytotoxic.
PLANT-GROWTH REGULATOR - Substance used for controlling or modifying plant-growth processes without appreciable phytotoxic effect.
POST-EMERGENCE TREATMENT - Application after emergence of the weed or planted crop.
PRE-EMERGENCE TREATMENT - Application before emergence of the weed or planted crop.
PRE-PLANT TREATMENT - Application before the crop is planted.
PROTECTANT - Pesticide applied to a plant in advance of the pathogen to prevent infection.
PUSTULE - Small blister-like elevation of epidermis created as spores form underneath and push outward.

R
RATE - The amount of pesticide material applied per unit area or per unit volume.
RESISTANCE - Inherent ability of a host to suppress, retard or prevent entry or subsequent activity of a pathogen or other injurious factor.
RESIDUAL HERBICIDE - Herbicide that persists in the soil and injures or kills germinating weed seedlings over a relatively short period of time. (See persistent herbicide.)
RHIZOME - Underground stem capable of sending out roots and leafy shoots.
RING SPOT - Circular area of chlorosis with a green center; a symptom of various virus diseases.
ROSETTE - Short, bunchy habit of plant growth.
RUNOFF - The liquid spray material that drips from the foliage of treated plants or from other treated surfaces. Also, the rainwater or irrigation water that leaves an area and may contain trace amounts of pesticide.
RUSSET - Brownish, roughened areas on the skin of fruit resulting from cork formation.

S
SANITATION - Term used for cultural methods that reduce inoculum.
SAPROPHYTE - Organism that feeds on dead organic matter as opposed to a parasite that feeds on living tissue.
SCAB - Roughened, crust-like diseased area on the surface of a plant organ.

SELECTIVE HERBICIDE - Herbicide that is more toxic to some plant species than to others.
SOIL APPLICATION - Pesticide applied mainly to the soil surface rather than to vegetation.
SOIL MOBILITY - Variable characteristic of a pesticide based on its chemical nature. Highly mobile pesticides leach rapidly through the soil and may contaminate groundwater. Immobile pesticides or those with low soil mobility remain attached to soil particles and are resistant to leaching.
SOIL STERILANT - Material which renders the soil incapable of supporting plant growth. Sterilization may be temporary or practically permanent.

SPORE - Tiny propagative unit of a fungus that functions as a seed but differs by not containing a pre-formed embryo.
SPOT TREATMENT - Pesticide applied over small, restricted area(s), of a larger area such as the treatment of weed patches within a larger field.
SPRAY DRIFT - The movement of airborne spray particles from the spray nozzle beyond the intended contact area.
STELE - The central cylinder inside the cortex of roots and stems of vascular plants.
STOLON - Runners or stems that develop roots and shoots at the tip or nodes, as in the strawberry plant.
STOOL - To throw out shoots; to tiller.
STYLET - The hollow feeding spear of a nematode.
SURFACTANT - Material which in pesticide formulations imparts emulsifiability, spreading, wetting, dispersability, or other surface-modifying properties.
SUSCEPTIBILITY - Magnitude or capacity to react to pesticide treatment.
SUSPENSION - Liquid or gas in which very fine solid particles are dispersed but not dissolved.
SYMPTOM - The external and internal reactions or alterations of a host as a result of a disease.
SYSTEMIC – Pesticide absorbed or injected into the plant and then spread internally through the plant.

T
TOTAL VEGETATION APPLICATION - Applying of single or multiple pesticide at one time or in sequence to provide pre-emergent and/or post emergent control of all plants. The term usually involves application to non-crop areas.
TRANSLOCATED HERBICIDE - Herbicide that is moved within the plant. Translocated herbicides may be either phloem-mobile or xylem-mobile, but the term is often used in a more restrictive sense to refer to herbicides that are moved in the phloem.

V
VASCULAR - The term applied to the water and nutrient conducting tissue of plants, also applied to a pathogen that grows in these conductive tissues.
VAPOR DRIFT - The movement of pesticide vapors from the area of application. Some pesticides, when applied at normal rates and normal temperatures, have a sufficiently high vapor pressure to cause them to change into vapor form. This may cause injury to susceptible plants away from the site of application. Note: Vapor injury and injury from spray drift are often hard to tell apart.
VIABLE - Alive, especially with reference to seeds capable of germinating.
VIROID - Low molecular weight ribonucleic acid (RNA) capable of infecting certain host cells, replicating, and causing disease.
VIRULENCE - The relative capacity and power of a pathogen to cause disease.
VIRUSES - Submicroscopic, filterable, obligate parasites. They are high molecular weight nucleoproteins capable of

multiplying and acting like living organisms in plant or animal cells.
VOLATILE - Quality that makes a compound evaporate or vaporize (change from a liquid to a gas) at ordinary temperatures on exposure to air.

W
WATER SOLUBLE CONCENTRATE - Liquid pesticide formulation that dissolves in water to form a true solution.
WETTING AGENT - Surfactant which, when added to a spray solution, causes it to spread over and wet plant surfaces more thoroughly.
WILT - Loss of rigidity and drooping of plant parts, generally caused by insufficient water in the plant.

Y
YELLOWS - Plant disease characterized by yellowing and stunting of the host plant.

Accepted December 03, 2012

The first pesticide synthesized was the dichloro diphenyl trichloroethane in 1874. In 1998, 20,000 commercial products were registered as «pesticides» by the US Environmental Agency of Protection. The classification, according to their toxicity, pesticides can be classified as extremely dangerous, highly dangerous, moderately dangerous and slightly dangerous. According to their median lifetime, they are classified as permanent, persistent, moderately persistent and not persistent. Given their chemical structure, they are classified in several groups, the most utilized of which are organochlorines, organophosphates, carbamates and pyrethrins. Agriculture, public health, structural pest control, industry, green area servicing and the maintenance of reservoirs of water are the main activities in which pesticides are currently employed. The main sources of pesticide exposure to humans are through the food chain, air, water, soil, flora and fauna. While acute poisoning generally affects farmers and industrial workers, chronic poisoning is more common in the general population. Pesticides are mainly absorbed through dermal, respiratory and oral pathways. Although absorption through the skin is prominent in the work environment, the general population are more at risk from ingestion and inhalation. Pesticides are distributed all around the human body through the bloodstream and are eliminated through urine, faces and exhaled air. The main techniques employed in the assessment of pesticides exposure are the history of exposure, the experts evaluation and environmental and biological monitoring.

Keywords: Pesticides, classification, uses, toxicology, exposure assessment.

INTRODUCTION

Synthetic pesticides emerge between 1930 and 1940 as a result of research aimed at developing chemical weapons that were originally tested in insects. One of the first compounds, dichlorodiphenyltrichloroethane (DDT) was synthesized by Zeidler in 1874, and its insecticidal properties were described by Paul Müller in 1939. DDT was first used during World War II to protect American soldiers carried diseases / by vector and was marketed in the U.S. in 1945 (WHO, 1990).

Since 1940 the production, marketing and ongoing use of various pesticides has increased to the present day, exposure to pesticides, either during their development, production or use can have adverse effects on health and the environment. These effects are not always related to immediate and apparent injuries, but can take even years to manifest (Zuniga and Gomez, 2006).

It originated, in turn, a race relentless in finding less toxic analogues to humans and more effective and selective with pests. However, the passages of a few years have become apparent adverse effects of pesticides on human health and on the environment.

*Corresponding Author E-mail: prietog@uaeh.edu.mx; sandycortes@gmail.com

Regardless of its benefits, it is clear that pesticides are toxic chemicals deliberately created to interfere in any particular biological system without actual selectivity. Simultaneously affect, and in varying degrees, both the "target species" as other categories of living beings, particularly humans. Although the general population is exposed to these compounds, pesticide exposure to various pollutants is associated with the occupation, farmers are in a high risk group, thus require biomonitoring studies to assess disease caused by acute and chronic exposure to pesticides (Castro et al., 2004).

The importance of genotoxic hazard biomonitoring is the identification of biomarkers that can define 2enotoxicity of prepatogénesis state and provide guidelines for the prevention of disease. Among the various damage to your genetic material, as a result of adverse environmental conditions, are point mutations and chromosomal, which can lead to cell transformation. Pesticide exposure can cause neuritis, psychiatric manifestations, hepatorenal disorders, neurological and neurodegenerative, immune, metabolic and endocrine. Similarly, it has been linked to increased incidence of leukemia and bladder cancer in farmers, following a genotoxic effect of some pesticides (Larrea et al., 2010).

Genotoxic compounds are those that act directly or indirectly on the DNA or clastogenic event. The genotoxic potential is a primary risk factor for chronic or long-term effects, such as reproductive effects and toxicity. Toxicological evidence of mutagenic and carcinogenic action of several pesticides and occupational or accidental exposure to large human populations to these compounds, have attracted the attention of many cytogenetic studies. A limited number of studies that seek to evaluate the genetic risk of occupational exposure established an association between occupational exposure to pesticides and the presence of chromosomal aberrations, sister chromatid exchanges and / or micronuclei (Au et al., 1999; Antocini et al., 2000; Pastor et al., 2001; Garaj and Zeljezi, 2002; Paz et al., 2002; Bolognesi, 2003; Paramjit, 2003; Ascarrunz et al., 2006).

Pesticide exposure may pose a potential risk to humans, causing neuritis, psychiatric manifestations, hepatorenales disorders, neurological, immunological, metabolic and endocrine. It has also been linked to increased incidence of leukemia and bladder cancer in farmers, following genotoxic effects of some pesticides. Results of this type have led many researchers to evaluate the genetic risk associated with pesticide exposure (Martin et al., 2003; Ascarrunz et al., 2006).

In this paper we review the different uses that have been given to pesticides, sources of exposure in the general population and toxicological characteristics, and review some techniques used to measure human exposure to these chemicals.

Overview of pesticides: Definition

Changes in the global environmental system produced by human activities result in an expenditure of energy and natural resources and growing increasingly untenable. Changes in land use for agriculture and livestock that can cause erosion and desertification, industrialization, urbanization, the expansion of motorized mobility, all of which are activities that produce large amounts of emissions to air, water and soil, and profound environmental degradation that affects society in many important ways. Among these is health that can be affected globally, on a spatial scale greater than in the case of local pollution, but can affect a number of people quite similar (Moreno and Urbina, 2008).

The pollution caused by heavy metals such as lead and mercury or chlorinated organic compounds (pesticides) can have severe health consequences. Both groups are associated with various cancers, especially those of the reproductive system, immune system depression, birth defects, sterility and neurobehavioral problems.

The United Nations Organization for Food and Agriculture (FAO) defines pesticides as any *substance or mixture of substances intended for preventing, destroying or controlling any pest, including vectors of human disease or animal species not unwanted plants or animals that cause damage or otherwise interfere in the production, processing, storage, transport or marketing of food, agricultural products, wood and wood products or animal feeds or which may be administered to animals for the control of insects , arachnids or other pests in or on their bodies* (CICOPLAFEST 1998; Badii and Landeros, 2007, Martinez and Gomez, 2007). Therefore, the purpose of pesticides is to destroy certain living organisms, as well as constituting a particular group of biocides that can reach a wide lethality.

The need to produce a greater quantity and quality of food by pest control resulted in intensive use of pesticides over the last 50 years (Garcia 1997, Chaverri et al., 2000). Pesticides are chemicals used by the very man to control agricultural pests and their correct application is the most accepted and effective for maximum production and quality of crops (Ferrer and Cabral, 1993; Bolognesi, 2003; Mansour , 2004, Martinez and Gomez, 2007). The increasing use and improper handling of these substances have raised concerns about the risks and damage that could result in the economy, the environment and public health (Jiménez 1995). Pesticides poisoning represent problems for handlers, implement or work with these products.

Pesticides are chemical groups more widely used by man, both to protect the production of harmful organisms and quality of crops and for the control of vectors and pests of public health, plus they have livestock use and domestic. These substances have been considered as

Table 1. Classification of pesticides according to toxicity, expressed as LD_{50} (mg/kg)

Class	Toxicity	Examples
Class IA	Extremely dangerous	Parathion, Dieldrin
Class IB	Highly dangerous	Eldrin, Dichlorvos
Class II	Moderately hazardous	DDT, Chlordane
Class III	Slightly hazardous	Malathion

potential mutagens because they contain ingredients to cause changes in deoxyribonucleic acid (DNA).

The World Health Organization (WHO) estimates that each year there are in the world around one million acute poisoning by pesticide exposure, with a fatality rate of 0.4% and 1.9%. Occupational exposure would be behind 70% of these fatalities. Moreover, sustained exposure to low doses of pesticides has been linked to a variety of disorders in the medium and long term, including various cancers, reproductive disorders and nervous system disorders, among other problems. The use of agrochemicals is widely widespread practice worldwide (Benitez et al., 2009).

Also, the WHO proposed classification based on their health risk, based on their toxic behavior in rats or other laboratory animals administered orally and dermally and estimating the median lethal dose (LD50) that produces death in 50 % of the exposed animals (WHO 1990). This ranking order from lowest to highest toxicity in numbers I through IV, being extremely toxic, highly toxic, moderately toxic, slightly toxic, respectively (CICOPLAFEST 1998, WHO 2004). However the most common way to classify them is based on their chemical structure, identifying four main groups: *organochlorines, organophosphates, carbamates, and pyrethroids*.

The former are very persistent in the environment and tend to accumulate in fatty tissues (Waliszewski et al., 2002, 2003a, b, 2004), are used in crops of grapes, lettuce, tomato, alfalfa, corn, rice, sorghum , cotton and wood, for preservation. The second man act on the central nervous system by inhibiting acetyl cholinesterase, an enzyme that modulates the amount and levels of the neurotransmitter acetylcholine, disrupting the nerve impulse by serine phosphorylation of the hydroxyl group in the active site of the enzyme. The third are less persistent than organochlorines and organophosphates and likewise the latter inhibit acetyl cholinesterase. However, in the case of carbamates action is fast and the kinetics of blocking is through the carbamylation of the enzyme by the covalent attachment of electrophilic groups steric carbamoyl sites of the enzyme (Martinez and Gomez, 2007) . The fourth group, also known as pyrethrins, act on the central nervous system causing changes in the dynamics of the Na + channels in the membrane of the nerve cell, causing it to increase its opening time prolonging sodium current through the membrane, in both insects and vertebrates (Perry et al., 1998; Sorgob and Vilanova, 2002).

The main producers and exporters of pesticides worldwide are Germany, USA, England, Switzerland, France, Japan and Italy, which supply all imports of the third world and according to the regulatory agencies, around 30% of the pesticides marketed in developing countries for agriculture and public health, with a value of 900 million U.S. dollars, do not meet internationally accepted quality standards. These pesticides often contain compounds or impurities that are restricted in other countries to be dangerous as they constitute a threat to human health and the environment (WHO 1990).

Classification of pesticides

Due to the large amount of chemicals and pesticides combinations of compounds have been classified for use in insecticides, miticides, herbicides, nematicides, fungicides, molluscicides and rodenticides. The World Health Organization proposed classification based on their health risk, based on their toxic behavior in rats and other laboratory animals by administering oral and dermal and estimating the median lethal dose (LD50) that produces death in 50% of exposed animals (WHO 1990). This ranking order from lowest to highest toxicity in numbers I through IV, being extremely toxic, highly toxic, moderately toxic, slightly toxic, respectively (CICOPLAFEST 1998, WHO 2004). Table 1 gives an idea of this classification.

According to its chemical structure, pesticides are classified into different families, ranging from organochlorine and organophosphorus compounds to inorganic compounds. In this paper, we refer only to some families of pesticides relevant for the damage they cause to human health and high demand for its use. The most common way to classify them based on their chemical structure is split into four main groups:

Organochlorine

Stable compounds are too persistent in the environment and tend to accumulate in fatty tissue (Waliszewski et al.,

2002, 2003 a, b, 2004). Its main use is in the eradication of disease vectors such as malaria, dengue and malaria. They are also used in cultivation of grapes, lettuce, tomato, alfalfa, corn, rice, sorghum, cotton and wood, for preservation. His way of exposure is mainly on insects by contact or by ingestion (Ferrer 2003). In humans these substances or their metabolites act primarily at the level of central nervous system altering the electrophysiological properties and enzymatic neuronal membranes, causing alterations in the kinetics of the flow of Na^+ and K^+ through the membrane of the nerve cell (Narahashi et al., 1992), resulting in the spread of multiple action potentials for each stimulus (Kamrin 1997, Ferrer 2003), causing symptoms such as seizures and acute poisoning death from respiratory arrest (Tordoir and Van Sittert 1994).

Organophosphates

They are esters derived from phosphoric acid. In man act on the central nervous system by inhibiting acetyl cholinesterase, an enzyme that modulates the amount and levels of the neurotransmitter acetylcholine, disrupting the nerve impulse by serine phosphorylation of the hydroxyl group in the active site of the enzyme (Fukuto, 1971, 2001 Keith, Sorgob Vilanova and 2002). The symptoms are causing loss of reflexes, headache, dizziness, nausea, convulsions, coma and even death (Sulbatos 1994, Perry et al., 1998). Also described with alkylating properties (Preussman et al., 1969, Fest and Schmidt 1973), which from the point of view of mutagenesis is paramount because they act directly on the deoxyribonucleic acid (DNA) adding alkyl groups methyl and ethyl mainly to the nitrogenous bases with nucleophilic groups capable of reacting with electrophiles (Wild 1975). Organophosphorus compounds are most commonly used in agriculture, most are insecticides and miticides, their way of joining these organizations is by ingestion and contact. They are used in vegetable crops, fruit trees, grains, cotton, sugarcane, among many others.

Carbamates

They are esters derived from acids or dimethyl N-methyl carbamic acid are used as insecticides, herbicides, fungicides and nematicides. Are less persistent than organochlorines and organophosphates and likewise the latter inhibit acetyl cholinesterase. However, in the case of carbamates action is fast and the kinetics of blocking is through the carbamylation of the enzyme by the covalent attachment of electrophilic groups steric carbamoyl sites of the enzyme (Moutchen-Dahmen et al., 1984).

Pyrethroids

They originate from natural insecticide derived from pyrethrum extract derived from chrysanthemum flowers, known as pyrethrins. Subsequently were obtained synthetically and are presently manufactured around 100 different commercial products (Sorgob and Vilanova 2002). Your income is the insects by contact or ingestion. They act on the central nervous system causing changes in the dynamics of the Na + channels in the membrane of the nerve cell, causing it to increase its opening time prolonging sodium current across the membrane in both insects and vertebrates (He, 1994, Perry et al., 1998). These events can lead to neuronal hyperexcitation (Narahashi et al., 1992, He, 1994, Narahashi, 1996, Perry et al., 1998).

Others

In addition other pesticides are as triazine herbicides, ureic, hormonal, amides, nitro compounds, benzimidazoles, ftalamidas, bipyridyl compounds, ethylene dibromide, sulfur containing compounds, copper or mercury, among others.

Use of pesticides

The given to pesticides has been multiple and varied, as shown in Table 2, which explains its ubiquity (Moses, 1993). Agriculture is the largest user of this type of compound used (Al-Saleh, 1994), consuming 85% of world production, to chemically control the various pests that reduce the quantity and quality of food crops and other vegetables. 10% of the total pesticides used in public health activities to control vector-borne diseases such as malaria, Chagas disease and dengue, among others. Also used to control rodents (Goldman, 1998), in water purification and in eradicating crops whose end products are illegal drugs. They are also used to control pests in large structures such as malls, buildings, airplanes, trains and boats. Apply in ornamental landscaping and recreational parks and gardens, to control the proliferation of insects, fungi and growth of grass and weeds. For the same purpose, are scattered along highways, railways and power lines towers with high voltage.

In nature reserves or artificial water pesticides used to prevent weed growth, algae, fungi and bacteria. In industry are widely used in the manufacture of electrical equipment, fridges, paints, carpets, paper, cardboard and food packaging materials, among others, to avoid these products in the growth of bacteria, fungi, algae, yeast or are damage by insect pests and/or rodents.

Table 2. Typical uses of pesticides

Activity	Use
Agriculture	Control of multiple crop pests in any stage
Public health	Control of disease vectors such as malaria, dengue, Chagas disease, onchocerciasis, plague, yellow fever, filariasis, trypanosomiasis, schistosomiasis, leishmaniasis and typhus. Control of pests (rodents) and eradication of plantations whose final product is a prohibited drug
Livestock and domestic care aniales	In the disinfection of sheep and pets like dogs and cats
Treatment of structure	Treatment of public and private buildings, offices, hospitals, hotels, cinemas, theaters, restaurants, schools, supermarkets, department stores, sports facilities, food warehouses and the rail industry and sea and air
Maintenance of green areas	Treatment of parks, gardens, playgrounds, golf courses, highways, railways, platforms, towers, high voltage lines and poles
Maintenance of water reserves	Treatment of large reserves of water, natural or artificial, dams, reservoirs, dams, reservoirs, ponds psicolas, canals, ponds and pools
Industries	In the manufacture of refrigerators, electrical equipment, paints, resins, adhesives, pastes, waxes, liquid limpiamentales, tents, sails for sailing, sports nets, mats, carpets and tapestries, the timber industry, packaging materials food, cardboard and paper multiple products. In the food industry for the preservation of fresh foods such as meat, pesacados, etc .
Home	Incorporated in products such as cosmetics, shampoos, soaps and insect repellents. They are used in the washing and drying of carpets, household disinfectants and care products for pets and plants, and the use of insecticides

Home is an area of particular interest: 90% of U.S. households' pesticide use and 83% of the total used is applied inside the house, the rest in surrounding areas. This practice in the world grows primarily from the specific use of insecticides because, of the 14 most consumed pesticides, 12 are insecticides. Moreover, it is common to use pesticides veiled, because without being cited in the regulatory label of the product and without warning the consumer about the precautions of use, are incorporated into products as cosmetics and shampoos to preserve the growth of fungi and bacteria, insect repellents and also in products for the care of pets and plants to attack or prevent insect infestation.

In Mexico it is used 60% of the 22 pesticides classified as harmful to health and the environment, 42% of which are manufactured in the country. Also used 30 pesticides (INEGI 1998). The regulation of pesticides in Mexico is done through different federal agencies: the transport by the Secretariat of Communications and Transportation, the impact on the environment by the Secretariat of Environment and Natural Resources, biological efficiency for agricultural use by the Secretariat of Agriculture, Livestock and Fisheries and the health aspects by the Ministry of Health (SEMARNAP 1996, Rosales Castillo 2001).

In addition to large amounts of pesticides imported by Mexico, there are plants in Coahuila, Chihuahua, Guanajuato, State of Mexico, Querétaro, Tlaxcala and Veracruz. The products for sale are classified according to their toxicity in 57% slightly toxic, 25% moderately toxic, highly toxic 9%, 9% extremely toxic (Perea, 2006).

In Mexico, the crops that apply the bulk of these products are corn, cotton, potatoes, peppers, tomatoes, beans, corn, avocado, coffee and snuff, in quantities ranging from 395 to 13.163 tons of pesticides to years (AMIPFAC 1995). In addition to the many products that are applied, there is the problem of collection, treatment and disposal of more than 12,000 empty pesticide containers, which are being addressed through the program "us preserve a clean field" trying to create awareness among farmers, regarding the safe handling and proper disposal of waste generated.

This program is being carried out in the State of Mexico through leaflets and radio messages transmitted in Sonora, Sinaloa, Querétaro, Guanajuato and Nayarit (AMIPFAC 2001, INE 2005). According to the Ministry of Health, 80% of cases of pesticide poisoning reported each year worldwide occur in developing countries.

In Mexico, employing 260 brands, of which 24 are prohibited and 13 restricted the main causes of poisoning poor forecasting and control measures. According to the Department of Epidemiology of the Ministry of Health, the number of cases of poisoning by pesticides significantly decreased from eight thousand to 2.532 between 1995 and 2001. However, the record also mentions that the following year the number increased slightly to settle at 2.802 in 2003 to 3.849 again rose cases and in 2005 was 3.898. However, the authorities recognize that there is

underreporting or "dark figure" in the number of cases of poisoning by the use of agrochemicals (Perea 2006). The indiscriminate use of pesticides and comprehensive has created serious problems for the environment and for the agencies "not white" as well as for men (CICOPLAFEST 1998).

The states with the highest pesticide use are Sinaloa, Veracruz, Jalisco, Nayarit, Colima, Sonora, Baja California, Tamaulipas, Michoacan, Tabasco, Mexico State and Puebla-Oaxaca, being approximately 80% of total pesticides which applies in these regions (Albert 2005).

Sources and exposure patterns

The environment is a major source of exposure to pesticides from farming. Approximately 47% of the applied product is deposited at or adjacent soil and water is dispersed in the atmosphere. This situation depends on weather conditions such as rain and wind direction and intensity, of geological and soil type and the presence of water currents, and other factors such as the formula and product presentation (liquid, powder, gel, gas, etc.) and application technique (air, land, etc.). Strong winds, high temperatures and unstable terrain favor the drag of the product, and the presentations powder, aerosol or smoke and, of course, aerial applications.

Other phenomena that favor environmental dissemination are photo degradation and volatilization, and leaching and washing soil surface, both related to the flow of water and rain. Work activity is important as a source of pesticide exposure in agricultural workers and their families, in chemical industry workers manufacturer of these products, fumigants, and in general, all those who formulated, manufactured, mixed, transported, loaded, stored or apply pesticides. The level of exposure and the likelihood of acute poisoning in these groups are substantially higher for continuous close contact with the chemicals. Although the period of contact with the agent are relatively short, they are still intense and repeated during the working day, causing toxic effects that vary with the type and amount of pesticide to which he was exposed, being relatively infrequent episodes of such accidental or intentional.

The exposure that affects the general population tends to be ubiquitous and crónica1. There are various types of pesticides for prolonged periods, from multiple sources and low doses penetrate the body using different routes. The main sources of exposure in the population are plant foods (fruits, vegetables, grains, legumes) or animal (beef, pork and its derivatives, fish, dairy products, eggs, etc.), And to a lesser extent water, air, soil, fauna and flora contaminated. So are the everyday industrial products that contain or are pesticides themselves and affecting directly or indirectly to human. It states that there is one segment of the general population free of exposure to these compounds and their potential adverse health effects (Barr et al., 1999).

Pesticides and its effects

According to estimates by the World Health Organization (WHO) each year between 500,000 and 1 million people are poisoned by pesticides and between 5,000 and 20,000 die. At least half of the intoxicated and 75% of those who die are agricultural workers, the rest is due to poisoning by eating contaminated food. In total between the two groups in mortality reached the figure of 220,000 deaths per year (WHO 1990, Eddleston et al., 2002).

Although pesticides have been developed to produce toxic effects in the fighting pests and although these effects may also potentially result in living organisms "nonwhite" of its action, the latter possibility will only occur if exposure these bodies reach sufficient levels to produce the toxic effect.

Therefore, besides knowing the physical, chemical and toxic pesticides, knowledge of each country or estimate potential exposures of humans and other organisms, which may occur in the localities in which they apply or you come to spread in the environment or through the food chain.

According to the type of toxicity, these chemicals affect the growth and survival of reproductive factors, and in the case of acute toxicity may cause death of exposed organisms (Campbell 1987). They have also been associated with long-term carcinogenicity, mutagenicity, reproductive and hormonal effects, among others. Agrochemicals able to induce changes in the genetic material of somatic and germinal tissue are considered mutagenic, contributing to the appearance of congenital malformations and cancer etiology (Wesseling ,1993, 1997). Epidemiological studies have associated with the cancer, gastric, skin, kidney, liver, prostate, testis in individuals exposed; besides sarcomas, leukemia, non-Hodgkin lymphoma, myeloma and others (Wesseling,1997).

Exposure to pesticides, either during development, production or use causing adverse effects on human health. These effects are not always related to immediate and apparent injuries, but can take even years to appear. Although the general population is exposed to these compounds, farmers are in a high risk group and therefore require biomonitoring studies to evaluate acute and chronic diseases caused by exposure to pesticides. Farm workers Irrigation District 03 (DR03) Mezquital Valley, Hidalgo, may be having genotoxic damage type for continuous and systematic use of pesticides. The amount of damage can be indicative of the need for continuous biomonitoring farmers occupationally exposed

to various mixtures of pesticides, using a battery of tests of genotoxicity. On the other hand, illustrates the need to implement general guidelines to minimize or prevent exposure.

Toxicological aspects of pesticides

Without ignoring the importance of pesticides in agriculture and in public health activities, are undeniable that generate toxic effects in humans. Its bioavailability in the body depends on its toxicokinetics: absorption, distribution, metabolism and elimination. These processes are influenced by external factors related to exposure patterns and chemicals (employment rate, temperature, type of pesticide, frequency, intensity and duration of exposure, etc..) and by factors inherent to the individual (age, sex, genetic endowment, health, nutritional status, lifestyle, main route of absorption, etc.) (Fait and Colosio, 1998). Diets low or lacking in protein and states of dehydration are factors that influence the severity of damage to health. In laboratory animals undergoing LPDs, the LD_{50} of some pesticides can decrease between 4 and 2100 times, a situation that could be extrapolated to humans. In this regard, a large proportion of the overall workforce and exposed live in underdeveloped or developing countries, where pesticide use is as common as nutritional deficiencies mentioned.

The absorption depends on the properties of the formulation and the route of entry, determining cross product body barriers to reach the blood or other tissue in particular. The pathways may be multiple and simultaneous, the most common being the dermal route, the digestive and respiratory. Pesticides penetrate the skin by passive diffusion across the stratum corneum. In the workplace the dermal route is the most important, because through it and depending on the surface of exposed skin, are absorbed significant amounts of various pesticides that vary in their level of absorption.

Organochlorine (OC) passing through the skin varies widely depending on the type of substance, for example, DDT is poorly absorbed, but others such as endrin, aldrin, dieldrin and heptachlor the largest share and penetrate faster. Can be found in the dermis residues chlordane compounds as parathion or even months after the last exposure. Already absorbed soluble pesticides diffuse through the fatty components of the skin and blood, while they do soluble molecules through the intracellular protein aceous material.

In the general population the most important route of absorption is the digestive system from ingestion of contaminated food and water, as mentioned in the previous section. Deliberate or accidental ingestion is relatively rare. The fineness and thinness of the alveolar epithelium favors gas exchange in the lung, but also allows rapid and efficient absorption of pesticides, which are captured by air quickly into the bloodstream. In the workplace the use of fumigants as gases, dusts, vapors and mists, puts the airway as the second most important. In the general population the airway is another important route of absorption, the widespread use of pesticides in farming areas by air, the wind drift to surrounding areas and the use of common household aerosol products, sprays, smoke bombs, etc.. favor the presence of the product in the environment continuously in small quantities.

Circulation transplacental and breastfeeding are considered transfer mechanisms rather than absorption, as many pesticides or their metabolites pass directly to new being through hematoplacentaria barrier and / or during breastfeeding. Pesticides are distributed in the body through the bloodstream. Liposoluble compounds bind to lipoproteins, whereas they do soluble molecules to proteins in plasma or blood remain dissolved. by affinity, the pesticide shall be specific organs or tissues, such as liver or kidney disease, and those that are lipophilic and accumulate in adipose tissue and nervous, as in the case of DDT and, in general, pesticides OC. Two types of reactions by which the pesticides are metabolized in the body: the first phase reactions (oxidation, reduction and hydrolysis), which are generally catalyzed by liver enzymes, and the second stage, which are the synthesis and conjugation. Metabolites resulting from the first stage are associated with endogenous molecules synthesizing water soluble components and readily removable by bile and urine, as water-soluble metabolites pyrethroids. The biotransformation of pesticides may result in reduced toxicity or substances chemically inactive, as with the final metabolite dimethoato. On the contrary, can be generated more toxically active substances than the parent compound, as is the case carbosulfan, carbofuran transformation into, or of parathion to paraoxon giving rise, metabolites with high affinity for DNA and mutagenic capability important. The human body eliminates pesticides in three main ways: urine, feces and exhaled air.

Some water-based materials, such as lindane and phenoxy type herbicides are easily eliminated through urine without undergoing any change. Bile is the primary means by which some soluble compounds such as DDT and other OC are eliminated in the stool. Fumigants reaching the body as gases or vapors are commonly removed by airway, as in the case of acrylonitrile or methyl bromide.

Risk assessment of pesticides

Risk assessment is a procedure to determine objectively and transparently, how much a pesticide under the conditions of use, as well as in various circumstances, including the worst-(different scenarios), is likely to cause

Tabala 3. Cytogenetic Biomonitoring studies through the use of tests for chromosomal aberrations (CA), micronuclei (MNs), sister chromatid exchange (SCE) and comet assay (C_A) in human populations exposed to pesticides

No. Individuals and Type of Exposure	Biomarker Used	Place of Study	Result	Reference
48 farm workers exposed to mixtures of carbaryl, mancozeb and 50 witnesses	MN ICH	Italy	Positive (MN) Negative (SCE)	Pasquini et al., 1996
23 growers exposed to a mixture of 100 pesticide formulations and 22 witnesses	CA MN SCE	Italy	Positive (SCE, CA) Negative (MN)	Scarpato et al., 1996
27 vineyard workers exposed to mixtures of pesticides mainly 2,4-D and 35 control individuals.	CA MN SCE	Former Yugoslavia	Positive (MN, CA) Negative (ICH)	Joksic et al., 1997
38 exposed to malathion in a pest eradication program and 16 witnesses	MN	Berkeley, U.S.	Negative	Titenko-Holland et al., 1997
80 workers exposed to mixtures of pesticides carbamic, dithiocarbamic, organochlorines, pyrethroids, phenoxyacetic acid, etc.. and 24 witnesses	CA	Hungary	Positive	Paldy et al., 1987
15 vintners exposed to copper sulfate and organochlorine and organophosphorus insecticides and 10 witnesses	CA	India	Positive	Rita et al., 1987
55 greenhouse workers exposed to mixtures of organophosphate and carbamate, pyrethroid acaricides and fungicides and 60 witnesses	CA	Hungary	Positive	Nehéz et al., 1988
25 horticulturists contact organochlorine insecticides, herbicides and organophosphorus ureic and 30 witnesses	CA SCE	India	Positive	Rupa et al., 1988
50 workers exposed in open field to carbamates, organophosphates and pyrethroids and 47 in the control group	CA SCE	India	Positive	Rupa et al., 1989
44 people exposed to the fungicide mancozeb and 30 witnesses	CA SCE	Czech Republic	Positive	Jablonika et al., 1989
27 workers exposed to mixtures of pesticides and 28 witnesses	SCE	Spain	Negative	Carbonell et al., 1990
26 workers exposed to mixtures of organochlorines, organophosphates and pyrethroids and 26 witnesses	CA	India	Positive	Rupa et al., 1991
32 growers exposed to mixtures of organophosphates, organochlorines, pyrethroids and 31 witnesses	CA SCE	Italia	Positive	De Ferrari et al., 1991
12 applicators of 2,4-D and 12 individuals in the control group	MN	Berkeley, U.S.	Positive	Holland et al., 2002
10 workers exposed to mixtures of pesticides atrazine, alachlor, cyanazine, 2,4-dichloro phenoxyacetic acid and malathion in industry and production of these 20 people in the control group	MN CA C_A	Croatia	Positive	Garaj-Vrhovac y Zeljezic 2002
107 growers of greenhouse and open field exposed to mixtures of organophosphates, pyrethroids, carbamates, benzimidazoles, amides and 61 witnesses	MN in peripheral blood lymphocytes	Italy	Positive	Bolognesi et al., 2002
20 workers exposed to mixtures of atrazine, 2-4D and malathion and 20 witnesses	CA C_A	Croatia	Positive	Zeljezic y Garaj-Vrhovac 2001

adverse effects human health and biota in organizations "not white" of its action. Also, by this method can predict the doses or concentrations of pesticides that have no effect on other receptors (PNEC for its acronym in English) and the concentrations that can be found in the environment: water, air and soil (PEC for short in

English), and calculate the Acceptable Daily Intake (ADI) and Total (TDI).

Added to this, and based on the magnitude of the risks identified, you can set priorities for action to prevent, control or remedy the damage caused by handling of pesticides. From these assessments, also, you can set the maximum permissible levels of pesticides in different media and maximum residue limits (MRLs) for agricultural products.

For new pesticides, the assessment of risks to identify if they are excessive, in which case you can be banned trade, or decide to marketing approval and to adopt measures to prevent risks and ensure safe handling . The risk assessment is based on knowledge of the properties that make them dangerous to pesticides and capable of causing damage to the health of humans and other living organisms, depending on exposure.

Genotoxic compounds and their effects

Genotoxic compounds are those that act directly or indirectly on the DNA or clastogenic event. The genotoxic potential is a primary risk factor for chronic or long-term effects, such as reproductive effects and toxicity. As shown in Table 3, a total of 17 studies reviewed, 15 reported positive differences in subjects occupationally exposed to pesticides compared to unexposed groups, based on their statistical significance, which permits the inference that these biomarkers are adequate evidence for this type of population monitoring. For chromosome aberrations (CA) work show positive results represent 100%, for sister chromatids exchange (SCE) and 62.5% for induction of micronuclei (MN) 75%. The comet assay (C_A) shows 100% success, but for being a technique that has recently begun to use in occupational studies, it is difficult to even determine their degree of reliability.

Toxicological evidence of mutagenic and carcinogenic action of several pesticides and occupational or accidental exposure to large human populations to these compounds, have attracted the attention of many cytogenetic studies. A limited number of studies that seek to evaluate the genetic risk of occupational exposure established an association between occupational exposure to pesticides and the presence of CA, SCE and/or MN (Au et al., 1999; Antonicci and Syllos, 2000, Pastor et al., 2001; Paz et al., 2002; Garaj and Zeljezic, 2002; Bolognesi, 2003; Paramjit et al., 2003). If such changes occur in proto-oncogenes or tumor suppressor genes, which are involved in cell growth and differentiation, may promote the development of cancer in the organ involved, contribute to premature aging, producing vascular diseases, autoimmune or degenerative. If they occur in the germ line, can cause reproductive problems (infertility) as increasing off-spring genetic diseases, monogenic and polygenic both (Bolognesi et al., 1997; Holsapple, 2002; Paramjit et al., 2003; Hagmar et al., 2004).

Some studies show that various agrochemical ingredients possess mutagenic properties, ie inducing mutations, chromosomal alterations or DNA damage and a marked correlation between genotoxicity and carcinogenicity testing and indicate that short-term genotoxicity are useful in predicting carcinogenicity (Table 3), since it has been found that most of genotoxic carcinogens are, therefore, genotoxicity could be a biomarker intermediate between onset of effect and early indicators of disease or susceptibility (Albertini et al., 2000; Ramirez and Cuenca, 2002; Poli et al., 2003).

Pesticide exposure may pose a potential risk to humans, causing neuritis, psychiatric manifestations, hepatorenales disorders, neurological, immunological, metabolic and endocrine. It has also been linked to increased incidence of leukemia and bladder cancer in farmers, following genotoxic effects of some pesticides. Results of this type have led many researchers to evaluate the genetic risk associated with pesticide exposure (Márquez et al., 2003; Larrea et al., 2010).

Currently used in various tests in vivo and in vitro in prokaryotic and eukaryotic cell systems with a high degree of sensitivity, to measure various types of DNA damage. These include proof of micronuclei (MN), chromosome aberrations (CA), sister chromatid exchange (SCE) and comet assay adducts by HPLC (Au et al., 1999; Antonicci and Syllos, 2000; Pastor et al., 2001; Paz et al., 2002; Garaj and Zeljezic, 2002; Bolognesi, 2003; Paramjit et al., 2003).

In general, SCE and comet tests are useful in this assessment, by its sensitivity to detect acute and chronic damage respectively, by the rapidity with which they perform and their potential usefulness in evaluating any eukaryotic cell population (Larrea et al., 2010). The test sample SCE high resolution in the evaluation of chronic damage, while the comet assay allows analysis of individual data and the use of extremely small tissue samples, among other advantages (Albertini et al., 2000; Garaj and Zeljezic, 2001; Poli et al., 2003; Marquez et al., 2003; Gabbianelli et al., 2004).

Chromosomal aberrations (CA) can be used as an early warning sign for the development of cancer, as the evidence of genotoxic damage correlated with the early stages of cancer in humans has been consolidated in cohort studies, and confirmed that detecting an increase in the frequency of CA, associated with exposure to genotoxic agents, can be used to estimate the carcinogenic risk. Although several studies have focused on populations occupationally exposed to pesticides, by analyzing different cytogenetic tests, some of the reported data are confusing and inconclusive. These studies require continuous assessment due to differences in the number, concentration and pesticide mixtures, and also the differences in protection measures, crop and

weather conditions among others (Garaj and Zeljezic, 2000; Bonassi et al., 2004).

Exposure meter

The measurement of the exposure and the possibility to establish a dose-response gradient are relevant aspects in studies of pesticides. Measuring exposure to pesticides in an individual or in a population is complex because it is influenced by factors such as the diversity of products sold, their indiscriminate use, multiple sources of exposure and variation in the intensity and duration of the an exposure period. All these aspects are beyond the control of the researcher and are generally lacks complete and timely information on them (Meinert et al., 2000). Several epidemiological studies have used a combined some measurement tools, such as exposure history, expert evaluation, environmental and biological monitoring, in order to achieve greater accuracy in measuring exposure.

The collection and analysis of retrospective exhibition is the most widely used measurement tool in epidemiological studies. The history of pesticide exposure is an indirect method that uses a structured individual questionnaire or some specific records, for homogeneous and systematic information on different aspects of exposure to these compounds over a period of time. Collect further data on socio demographic variables, confounding variables and other variables of interest. Both questionnaires as records are designed primarily for labor studies, but as the case is suitable for application in other populations. A common practice to extend or validate information initially obtained from a questionnaire, is the subsequent collection of detailed data on exposure (specific agricultural activity, type of application equipment, personal protective devices, previous damage to health, personal hygiene, etc.) or use of records such as purchase, or the management and use of pesticide products that have been implemented in various companies in the agricultural industry (Olshan and Daniels, 2000). More complete information on the history of exposure will result in a more accurate classification of subjects, reducing the potential effects of recall bias and improve the sensitivity and specificity.

The history of contact with pesticides are important but not sufficient to characterize exposure should be supplemented with information obtained by other techniques such as environmental monitoring and / or biological, to more accurately determine the level of exposure of the study subjects. Depending on the type of study can be contrasted with the current limits.

Biomarkers used for cytogenetic biomonitoring of populations exposed to pesticides

Biological markers or biomarkers are the biochemical, physiological or morphological measurable occurring in a biological system and interpreted marker reflecting or exposure to a toxic agent (Garte and Bonassi 2005). Biomarkers are used as indicators of health status or risk to disease and are used in both in vitro and in vivo that may include humans. Biomarkers are generally classified into three particular types (although some of them may be difficult to classify): exposure, susceptibility and effect and are a useful tool to assess the potential risk of different exposures. At the individual level can be used to support or refute the diagnosis of a particular type of poisoning or other adverse effects induced by chemicals.

Biomonitoring studies in agricultural populations published since the early 70s indicate mixed results, has been used for a wide variety of cytogenetic biomarkers and heterogeneous populations across the studies (Paldy et al., 1987, Rupa et al., 1989 , De Ferrari et al., 1991, Carbonell et al., 1993 Bolognesi et al., 2002). It is also important to consider that studies of pesticide exposure and genotoxic effect must take into account the reliability of injury exposure, the strength of the studies, the similarity of the control group and the protocols used for genotoxicity (Bull *et al .* 2006).

The cytogenetic damage causes changes and alterations in the number or structure of chromosomes, these effects have been evaluated using biomarkers as chromosome aberrations (CA), micronuclei (MN) and sister chromatid exchange (SCE) has also been possible to determine disorders that are manifested by changes in cell proliferation kinetics, which can be observed and evaluated during mitosis (Yakovenko and Zhurkov 1976, Pearson et al., 1981, Rupa et al., 1989, Diaz et al., 1990). Also we used the alkaline single cell electrophoresis or comet assay to assess DNA damage and repair in both in vitro studies and in vivo (Moretti et al., 2000).

One of the most important problems is occupational exposure to these compounds, so many studies have been conducted in order to assess the risk involved, especially for farm workers, through the evidence of chromosomal aberrations (CA), micronuclei (MN), sister chromatid exchange (SCE) and comet assay (C_A), the results have been controversial, because there are several factors that can cause differences. These may be the chemical group to which they belong pesticides, technical formulation and the active ingredient which is the product, the type of exposure (acute or chronic), the time that the individual has been exposed, the way it has been the contact (direct or indirect), the amount used, exposure to mixtures, the weather and the time of year that are sprinkled, the age of people, among other factors.

The CA is an error during meiosis the gametes or the first division of the egg and causes an abnormality of the number or structure of chromosomes and can be observed in the metaphase of the cell cycle and that originate in breakage (clastogenic processes) of the unrepaired DNA chains or poorly repaired, among

other factors (Nussbaum et al., 2008).

The MN are chromosome fragments or whole chromosomes spontaneously or because of broken chromosomes agents such as radiation (agents that are called clastogens) or damaging the mitotic spindle, such as vinchrystine (aneuploidogens) fall outside the core during mitosis. Are known in the field of hematology as Howell-Jolly bodies and is generally round shape or almond with a diameter ranging from 0.4 to 1.6 microns. Its formation is based on that in the anaphase any chromosomal fragment that does not have centromere can not join a core lacking the essential element bearings in the spindle apparatus. After telophase, normal chromosomes and having centromere fragments, give rise to daughter cells nuclei, but lagging element, which may be fragments or whole chromosomes, are included in the cytoplasm of cells daughters, and a proportion of them is transformed into one or more secondary cores. Such nuclei are much smaller than the core, and hence the name "micronucleus". Then, if the test compound is a clastogen, MN will form small, but it is a aneuploidogen, which will observe the formation of MN. Among the variety of cells can be identified in peripheral blood and buccal mucosa by a smear (Zuniga and Gomez, 2006).

The SCE is a normal cellular event that occurs during the S phase of mitosis. Represents the symmetrical exchange between homologous loci of replication products. These exchanges are produced by breakdown and subsequent repair of DNA, at loci which are exchanged during the synthesis phase of the cell cycle. Occur without loss of DNA or chromosome morphology changes and may detect in metaphase chromosome preparations obtained from cultures spiked with a base analogue of DNA (Perez et al., 1999; Morales et al., 2007).

C_A is a biomarker fast, simple, and sensitive visual known as unicellular alkaline electrophoresis which is used to measure and analyze the DNA breaks. Differences detected intracellular damage repair processes virtually all cells (Speit and Hartmann 2006). The EC kite is to quantify the damage induced in the DNA of cells which are embedded in agarose, lysed and then subjected to electrophoresis in alkaline pH, thus making the chromosome fragments are directed towards the anode and the tail are disclosed as of a comet, which is displayed after staining with a fluorescent dye (Tice et al., 2000; Cossio et al., 2004). The ability of DNA migration depends on the number of breaks produced by the agent in question (Garaj and Zeljezic 2001), so each damaged cell has the appearance of a comet with a head and a tail and bright fluorescent cells not appear to have been damaged intact nuclei without tails (Möller 2006).

It is known that the active ingredients used in the production of commercial pesticides have harmful health effects, both final consumers of food treated as in exposed workers (Ballantyne, 1994) and between effects caused by pesticides, the most relevant genotoxicity. There are numerous studies linking the use of glyphosate with damage to genetic material highlighting the occurrence of birth defects, cancer and abortions. The mechanism is given by the genotoxicity that pesticides have shown, and glyphosate is no exception.

In a recent technical report submitted to the Council of State of Colombia by Mark Chernaik, eminent American toxicologist stated that "glyphosate exposure represents a risk in pregnant women." This statement is based on the study by Arbuckle (2001) which found a higher incidence of spontaneous abortions between 0:19 weeks of pregnancy in women exposed to glyphosate initiated before pregnancy. Similarly found glyphosate genetic effects in vitro cultures of bovine and human lymphocytes. In a study in Ontario, Canada, on the relationship between exposure to various types of pesticides and the occurrence of spontaneous abortions in farm households, 2,110 women were evaluated on the basis of 3.936 pregnancies, and included 395 spontaneous abortions. One of the interesting aspects of this study is that there is more interaction between pesticides to which a person is exposed as time passes. Usually, farmers and their families are exposed to a variety of different chemical families of pesticides (organophosphates, carbamates, etc..) These interactions cause an increased incidence of fetal death. Furthermore the chemical nature of the pesticide, the toxicity of the time depends also on the exposure occurs. There are critical times of fetal development and reproductive system in which pesticides are more toxic (Chernaik, 2003).

Biomonitoring studies

Pesticide exposure interferes with human health, because there are problems of morbidity and quality of family life genotoxic derivatives to generate birth defects, carcinogenic, among others, exposure to pesticides does not exempt any age group or gender, variously affects the exposed (Badii et al., 2007; Yucra et al., 2008).

The check for induction of DNA damage is performed by various tests, but human biomonitoring studies by cytogenetic assays are the most commonly used. The objectives of the biomonitoring as part of the genetic risk assessment are detecting exposure to environmental genotoxins, the determination of genotoxic effects in vivo (Bonassi et al., 2004) and the identification of biomarkers of genotoxicity can define a state of prepatogénesis and provide guidelines for disease prevention. Within genotoxicity biomarkers that have been used widely, are the frequency of sister chromatid exchange (SCE), micronuclei (MNs), chromosome aberrations (CA) and comet assay (C_A) (Bolognesi et al., 1997; Vigreux et al. 1998; Garaj and Zeljezic 2000; Pastor et al., 2001;

Holsapple, 2002).

This study will assess the genotoxic damage and measure the genetic risk in farmworker populations occupationally exposed to a mixture of pesticides, through 4 different methods: sister chromatid exchange (SCE) analysis of chromosomal aberrations (CA), micronuclei (MN) and comet assay (C_A).

CONCLUSIONS

The extensive application of pesticides is a common practice around the world. Although the production and marketing of certain pesticides harmful to humans have been banned, other products continue to be used, without knowing fully the negative impact that these compounds may have on ecosystems and public health. Evidence indicates that pesticides pose a risk to public health, so it is necessary to conduct more studies using different models and indicators to assess the potential risks to health and the ecosystem. Therefore, unintelligent use of pesticides has led to reduced connectivity (trophic interaction between organisms), loss of biodiversity, ecological imbalance and environmental stability decreased. Consequently, man, by the lack of rational use of pesticides, has been and is threatening the sustainability.

This literature review shows that more tests or biomarkers used to evaluate the genotoxic effect of pesticides are MN, CA, SCE and recently the C_A. This is based on studies conducted by researchers from different countries of the world, which provide scientific evidence indicates positive correlations between exposure time, dose and high frequency CA, MN, SCE and C_A. However, it is common to find discrepancies in results across studies, which may be due to the age of people, the use of mixtures of pesticides, genetic polymorphism, forms of application, level of genotoxic compounds , the characteristics of the spray (enclosed or open field) or the interaction of these situations. Considering this, it is important the introduction of agricultural practices that reduce pesticide use in this sense is vital to incorporate measures of biological control and integrated pest management. It is also essential to intensify efforts in training and updating of technical staff, laborers and farmers, and to strengthen prevention and education to the community.

Cytogenetic monitoring should be considered as an integral part of good medical surveillance on people in contact with pesticides, since it allows to evaluate the potential risk of occupational exposures, which would take the necessary measures for early identification of genetic risk. Monitoring of human populations by analysis of chromosomal aberrations and sister chromatid exchanges in peripheral blood culture and micronucleus and comet.

**These pesticides are among the top 10 most heavily used pesticides in the home and garden sector from 2006-2007, according to the latest sales and usage data available from EPA (2011), available at http://www.epa.gov/opp00001/pestsales/07pestsales/market_estimates2007.pdf.*
† EPA lists all synthetic pyrethroids under the same category. While all synthetic pyrethroids have similar toxicological profiles, some may be more or less toxic in certain categories than others. See Beyond Pesticides' synthetic pyrethroid fact sheet at bit.ly/TLBuP8 for additional information.
‡ Imidacloprid is a systemic insecticide in the neonicotinoid chemical class, which is linked to bee decline.

Description

Most toxicity determinations based on interpretations and conclusions of studies by university, government, or organization databases. Empty cells may refer to either insufficient data or if the chemical is considered relatively non-toxic based on currently available data.

The list of 30 commonly used lawn chemicals is based on information provided by the General Accounting Office 1990 Report, "Lawn Care Pesticides: Risks Remain Uncertain While Prohibited Safety Claims Continue," U.S. Environmental Protection Agency (EPA) National Pesticide Survey (1990), Farm Chemicals Handbook (1989), The National Home and Garden Pesticide Use Survey by Research Triangle Institute, NC (1992), multiple state reports, current EPA Environmental Impact Statements, and Risk Assessments, EPA national sales and usage data, best-selling products at Lowe's and Home Depot, and Beyond Pesticides' information requests.

For more information on hazards associated with pesticides, please see Beyond Pesticides' *Gateway on Pesticide Hazards and Safe Pest Management* at www.beyondpesticides.org/gateway. For questions and other inquiries, please contact our office at 202-543-5450, email info@beyondpesticides.org or visit us on the web at www.beyondpesticides.org.

Pesticides

Pesticides - These are different forms of chemicals that are used in agriculture to kill pests and protect crops.

Introduction

Agricultural products are vulnerable to various pests that destroy crops. They account to huge loss of crop yields. This results in suffering for both the farmer and the workers. It becomes important for both the farmer and his workers to work together to ensure that crops are not destroyed. It is also important that they both work together to ensure that in the course of work activities workers are not exposed to risks that may cause ill health, injuries and even death. Therefore the knowledge and understanding of pesticides used in agriculture is an important step in applying good health and safety standards.

The application of pesticides affects workers and their families. Most farm workers and their families live on the farms or near the farms. Environmental problems are also caused by use, overuse or misuse of these pesticides.

What are pesticides?

These are different forms of chemicals that are used in agriculture to kill pests and protect crops. Many people call them poisons. Others call pesticides agrochemicals, crop or plant protection products. The primary aim of pesticides is to control diseases, insects and weeds in agricultural crops. But these pesticides are also harmful to humans.

What are agricultural pests?

There are different pests that destroy crops in agriculture such as:

- Weeds or unwanted plants
- Insects
- Rodents
- Fungi.

Types of pesticides

Many different types of pesticides are used on farms. They are grouped (classified) according to their use" or pests they intend to kill. The following are the most common types used in South Africa:

- Herbicides - are meant to kill weeds
- Insecticides - are meant to kill insects
- Fungicides- are meant to kill fungi
- Rodenticides- are meant to kill rats, mice and other pest species of rodents.

These different pesticides are applied in agricultural activities such as weed killing, crop protection, stock protection, soil fumigation, stock disinfection, etc.

Forms of pesticides

There are three main forms of pesticides. They are:

- Liquids – usually mixed with water and then sprayed
- Solids - usually they are pastes, pellets, dust and powder and may be applied directly as solids. They may also be turned into other forms
- Gases- usually they are tiny particles.

Effects of pesticides

Use, overuse and misuse of pesticides have effects on humans and the environment. Their effects on humans are either acute or chronic effects causing some of the following:

- Damage to the nerves
- Damage to the lungs
- Cancer
- Sterility
- Birth defects
- Allergic reactions
- Fatal poisoning.

In short, they cause injuries, ill health, death and environmental degradation. It therefore becomes necessary to understand how pesticides enter the human body.

How pesticides enter the body (routes of entry)

Pesticides enter human bodies through four main ways. Most people call this the chemical route of entry.

The four routes of entry are:

- Through the skin – It is called absorption or dermal. The pesticides enter the body through the pores used for releasing sweat from the body. It usually happens when a worker mixes or sprays pesticides or becomes exposed without wearing suitable personal protective clothing

- Through the mouth by swallowing - It is called ingestion or oral. This normally happens when eating food and drinks on the field or dust swallowed with saliva or smoking cigarettes. Sometimes chemical containers are used to carry drinking water

- By breathing in fumes or vapours – Most people calls it inhalation. The pesticides are breathed in as dust, fumes, vapours or gasses especially if not wearing suitable personal protective equipment

- Through the eyes- This is called ocular. In mixing or spraying work activities without suitable protective clothing, splashes of dust or vapours may enter through the eyes.

Prevention and control

Some of the steps that are import in the prevention and control of pesticides hazards are outlined as follows:

The wearing of personal protection equipment (PPE) is of absolute importance at all times when pesticides are used.

1. The first step before the use of pesticides is for the employer to do a risk assessment

- Identify potential hazards
- Evaluate the risks
- Work out suitable preventive and control measures.

2. Eliminate the risk

- Use another method other than pesticide to deal with pests
- Use a pesticide that is less hazardous.

3. Control the risk

Use technical and engineering controls such as:

- Sealed mixing and filling systems for tractor-mounted spraying
- Pesticides with tractor cabs fitted with approved, charcoal-based pesticides filters which absorbs it when it enters into the cab.

4. Safe system of work

Put in place a safe system of work such as:

- Workers are removed from areas before beginning of spraying
- Re-entry periods are known and adhered to
- The spray equipment are regularly checked to ensure that they are in good working order and properly calibrated
- Ensure effective supervision
- Health and safety legal standards are adhered to.

5. Information and training

- Ensure that all workers are trained on occupational health and safety
- Those specifically working with pesticides are given special training on equipment and pesticides they use. They are trained on hazards associated with pesticides and risk prevention/control measures
- Workers should be trained on information on labels and Material Safety Data Sheets (MSDS). Ensure that pesticides are supplied with and are in the language understandable by the user. Labels contain the information:

Labels, usually stuck directly on to containers have some of the following information:

1. Product information : trade/brand name; manufacturer/supplier's name; addresses; type of formulation; emergency phone numbers.
2. Hazardous ingredients: active ingredients; other chemical formulation; all identified by a chemical name(s).
3. Toxicological properties: health effects; environmental effects; hazard warning symbols.
4. User information: direction for use; dose rates; mixing instructions; application rates; approved tank mixes.
5. Environmental/crop/pest information: range of crops; types of livestock; pest range; tolerant or resistance species; warning on possible crop damage; harvest intervals.
6. Precaution/preventive measures: technical/ engineering control; other safety information; medical advice or warning; washing and disposal of containers.
7. Operator protective measures.
8. First aid measures.

MSDS can be obtained free of charge from the manufacturer, importer or supplier of the product. They are not automatically supplied with the product.

The main information in MSDS is the following:

1. Product information: trade/brand name, manufacturer/suppliers names and addresses, and emergency phone numbers.
2. Hazardous ingredients: active ingredients by chemical(s) name(s).
3. Physical data.
4. Fire or explosion data.
5. Reactivity data: information on the chemical instability of the product and substances it may react with.
6. Toxicological properties: health and environmental effects.
7. Preventive/control measures.
8. First Aid measures.
9. Preparation information: Who is responsible for preparation and data of preparation of the MSDS.

Does the pesticide pose problems to the livestock and the environment (fish, rivers, birds, bees, or other water sources)?
Is it possible to damage neighbouring crops and/or villages.

6. Hygiene and health surveillance

- Provision of suitable washing facilities on the farm/plantation yard where users could wash themselves after spraying
- Availability of First Aid facilities.

7. Provision, use, and maintenance/replacement of personal protective equipment

Personal protective equipment (PPE) includes any clothes, material or devices meant to protect exposure to pesticides.

This is the least effective means of protecting workers against risks and it complements other methods of control. These include the following:

- Gloves
- Apron
- Boots
- Face shield
- Head gear
- Respiratory protective equipment (RPE).

Other key points when working with pesticides

1. Transfer/decanting

- Discourage repackaging of pesticides under any circumstances
- In case those pesticides are transferred into another container, it should only be done by trained workers under suitable supervision
- The new container must then be appropriately labelled.

2. Transport

When transporting pesticides on the farm, ensure:

- That random stacking is avoided
- Pesticides are separated from other materials and people
- Pesticides are not carried alongside the driver in the vehicle/tractor cab.

3. Storage

Pesticides should have a well constructed store that is properly maintained with a safe system of work for those who access it.

The following are key points for storage:

- Site to allow easy access for delivery and loading
- Storage facilities must be constructed away from houses, livestock, flammable materials and water or areas liable for flooding
- Separated from stocks such as fertilizers, flammable materials and crops/food
- Provided with natural ventilation
- Fitted with strong and durable shelving.

4. Disposal

Proper disposal of pesticides is encouraged. Leaving pesticides in the field or dumping them in watercourses is not allowed.

Some of the key points in disposal of pesticides:

- All containers should be rinsed out, at least three times and the washings disposed
- Storage of containers before disposal should be well defined in a demarcated area
- Labels should not be disfigured.

Leaving pesticides in the field or dumping them in watercourses is not allowed.

July 2008 version

1

<<NOTE TO USER: Please add details of the date, time, place and sponsorship of the meeting for which you are using this presentation in the space indicated.>>

<<NOTE TO USER: This is a large set of slides from which the presenter should select the most relevant ones to use in a specific presentation. These slides cover many facets of the problem. Present only those slides that apply most directly to the local situation in the region.>>

LEARNING OBJECTIVES

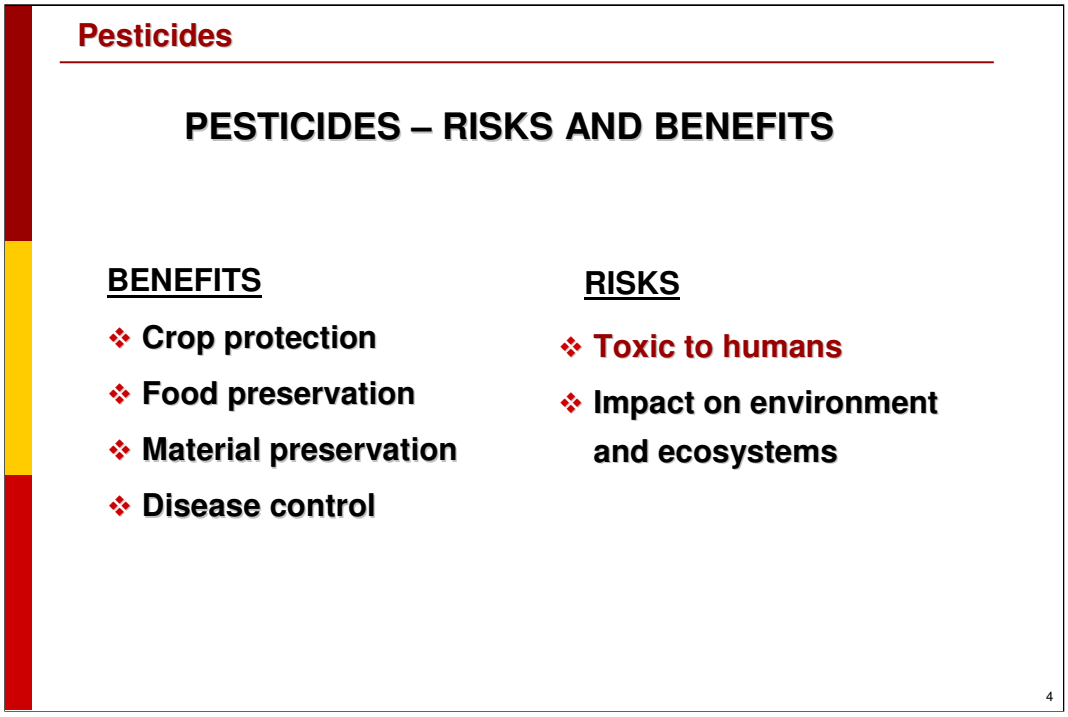
- Learn about pesticides – what they are and what are the risks they may pose?
- Identify the scenarios – where and when are children exposed?
- Recognize signs, symptoms and diseases that may be related to pesticide exposure in children
- Know how to prevent and treat children's pesticide exposure

<<READ SLIDE.>>

OVERVIEW

- What are pesticides?
- Origin, environmental transport and fate of pesticides
- Routes and circumstances of exposure
- Exposure levels
- Toxicokinetics and toxicodynamics
- Target organs and systems
- Diagnosis and treatment of poisoning
- Prevention of pesticide exposure and poisoning

<<READ SLIDE.>>



Pesticides have numerous beneficial effects. These include crop protection, preservation of food and materials and prevention of vector-borne diseases.

For example pesticides may be used in the prevention of malaria, which kills up to 1 million children per year, and for preventing other vector-borne diseases such as dengue, leishmaniasis and Japanese encephalitis.

Pesticides are toxic by design – they are BIOCIDES, designed to kill, reduce or repel insects, weeds, rodents, fungi or other organisms that can threaten public health and the economy.

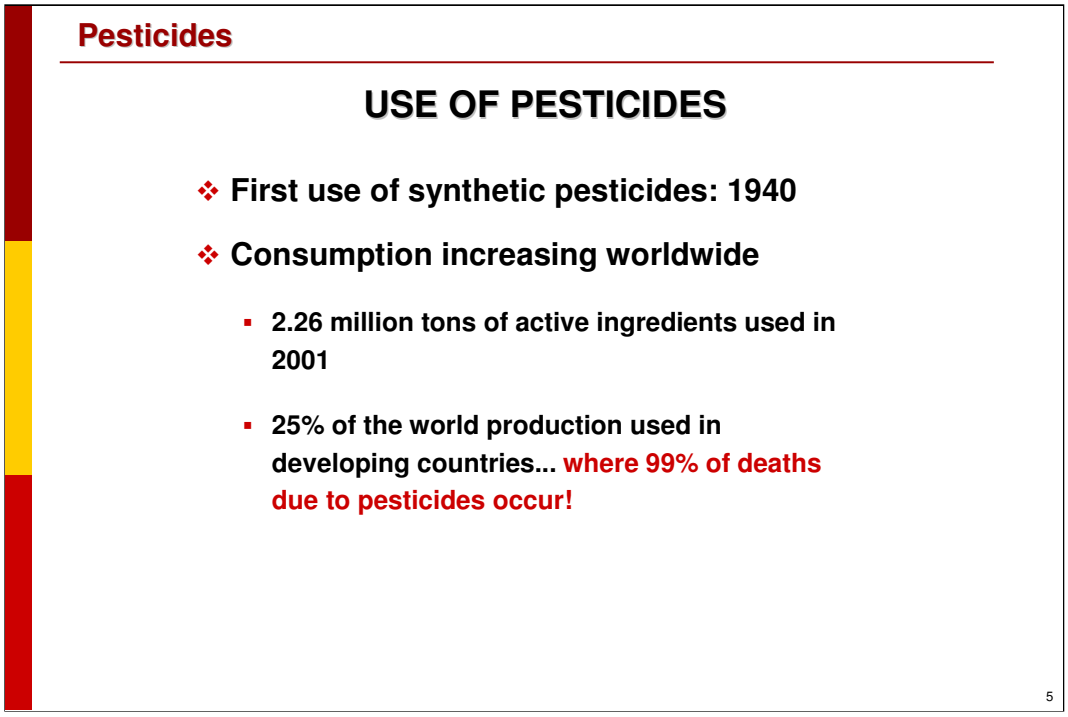
Their mode of action is by targeting systems or enzymes in the pests which may be identical or very similar to systems or enzymes in human beings and therefore, they pose risks to human health and the environment.

Pesticides are ubiquitous in the environment and most are synthetic.

There is growing concern about children's exposure to pesticides and their special susceptibility. Children are not little adults, and may have higher exposures and greater vulnerability at both high and low levels of exposure.

Ref:

•National Resource Council. *Pesticides in the diets of infants and children*. National Academy Press, Washington, DC, 1993.



<<READ SLIDE.>>

a) First use of synthetic pesticides: 1940

b) Consumption increased substantially over time, for example, in the USA, the use of pesticides doubled from 1960 to 1980, but total use has since remained stable or fallen. Most pesticides are used in agriculture, but in 1999 about 74% of households in USA were reported to use at least one pesticide in the home.

c) Use has risen in developing countries and the fastest growing markets in Africa, Asia, South and Central America, Eastern Mediterranean. There is a high pesticide use on crops grown for export (Dr. N. Besbelli, WHO, personal communication).

d) Although developing countries use only 25% of the pesticides produced worldwide, they experience 99% of the deaths. This is because use of pesticides tends to be more intense and unsafe, and regulatory, health and education systems are weaker in developing countries.

Pesticides are used in different settings.

<<READ SLIDE.>>

•It is important to consider the presentation, concentration and formulation of the products, as the toxic effects depend on the physical state of the product and also on the characteristics of the solvent or other substances contained in the formulation. "Chalk" pesticide has been sold illegally in the USA, it may contain pyrethroids. (See US EPA website.)

•The rate of absorption depends upon the presentation of the product: volatile pesticides and fine powders are more easily inhaled than dense products and coarse granulated materials.

•Concentrated solutions are much more dangerous than diluted ones; solid baits may be colourful, attractive and sweet, and may be easily ingested by toddlers.

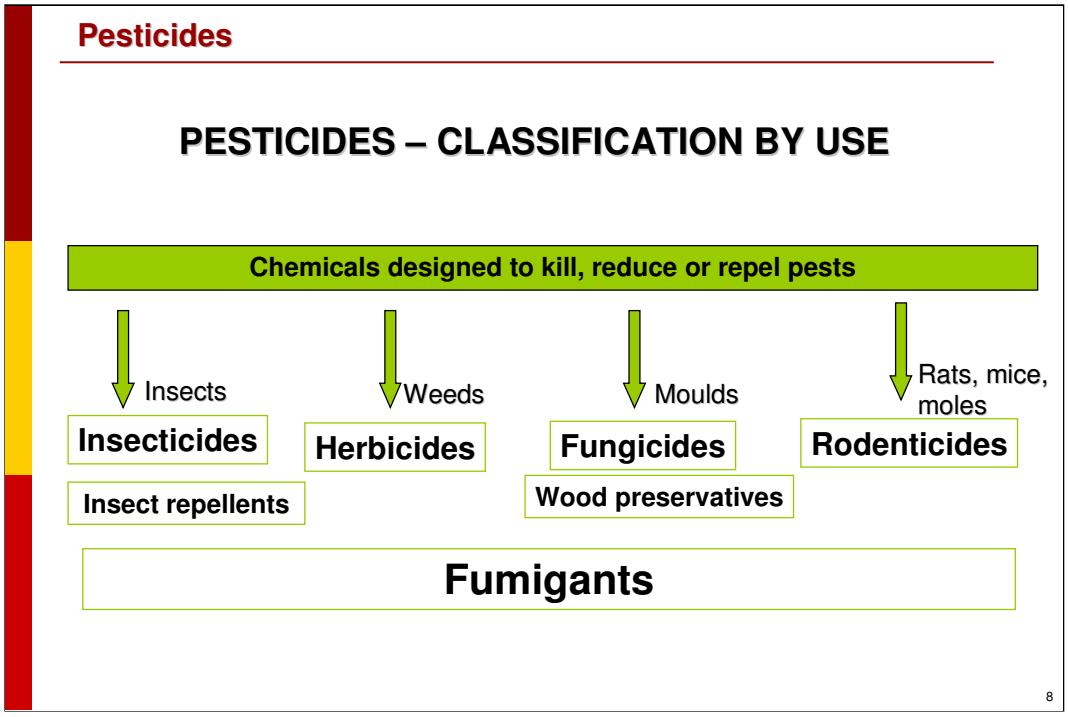
•In some cases, if the concentration of the active compound is less than 2% (as is generally the case for pesticides for household use), the toxicity in cases of human exposure may be due to the solvent (e.g. kerosene or paraffin) and not to the active ingredient.

Refs:

•IPCS. *The WHO Recommended Classification of pesticides by hazard, Guidelines to Classification 2000–2002* (www.inchem.org/documents/pds/pdsother/class.pdf)

•Tomlin C. *The pesticide manual, 11th ed.* British Crop Protection Council Publications, 1997.

•"Chalk" pesticides information at www.epa.gov/opp00001/health/illegalproducts/chalk.htm



There is a large variety of pesticides designed to kill specific pests – those most widely used are listed below.

•**Insecticides** (for killing insects) such as organochlorines, organophosphates and carbamates. This category also includes insect repellents such as diethyltoluamide (DEET) and citronella (of natural origin).

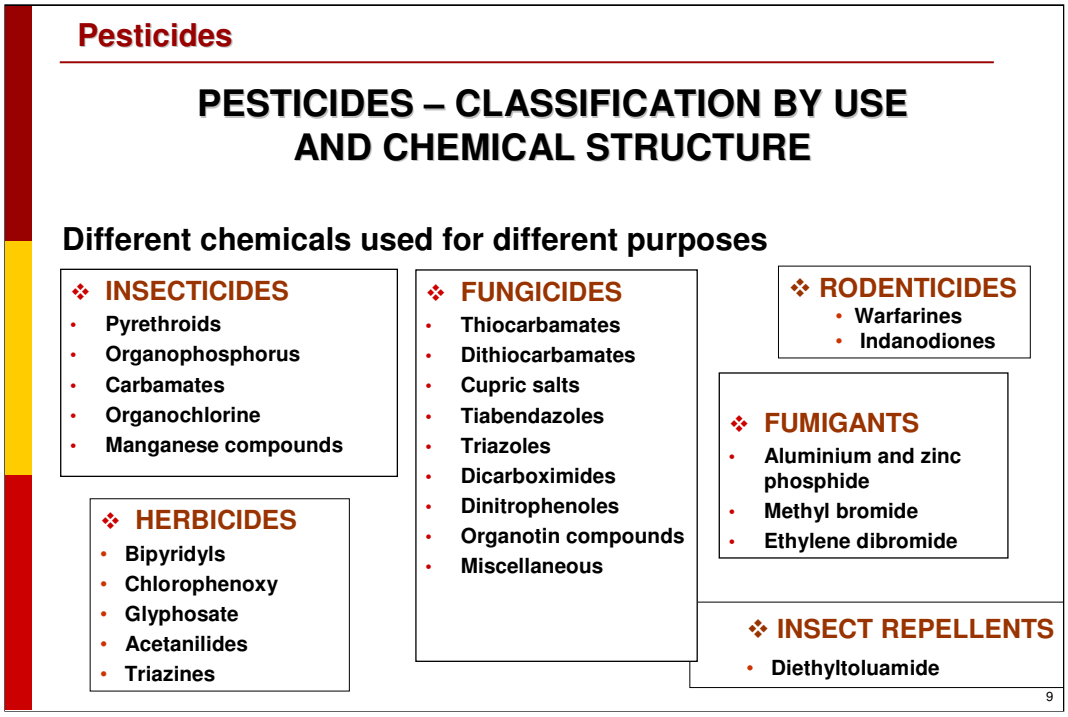
•**Herbicides** or weedkillers (e.g. paraquat, glyphosate and propanil).

•**Fungicides** (to kill mould or fungi): when applied to wood, they are called wood preservatives.

•**Rodenticides** (to kill mice, rats, moles and other rodents).

•**Fumigants** are pesticides that exist as a gas or a vapour at room temperature and may be used as insecticides, fungicides or rodenticides, especially in closed storage places – as they kill every living organism. They are extremely toxic, due to their physical properties, rapid environmental dissemination and human or animal absorption (examples include cyanide, aluminium phosphate and methyl bromide).

•**Other pesticides** include algaecides (to kill algae), miticides (to kill moths) and acaricides (to kill ticks).



There are many groups of chemicals used as pesticides. There are hundreds of different active principles or main ingredients of pesticide groups (e.g. approximately 300 in Uruguay and 900 in the USA).

<<NOTE TO READER: insert the number in your country/region.>>

Some domestic, agricultural or veterinary products may contain more than one chemical belonging to the same or a different chemical group.

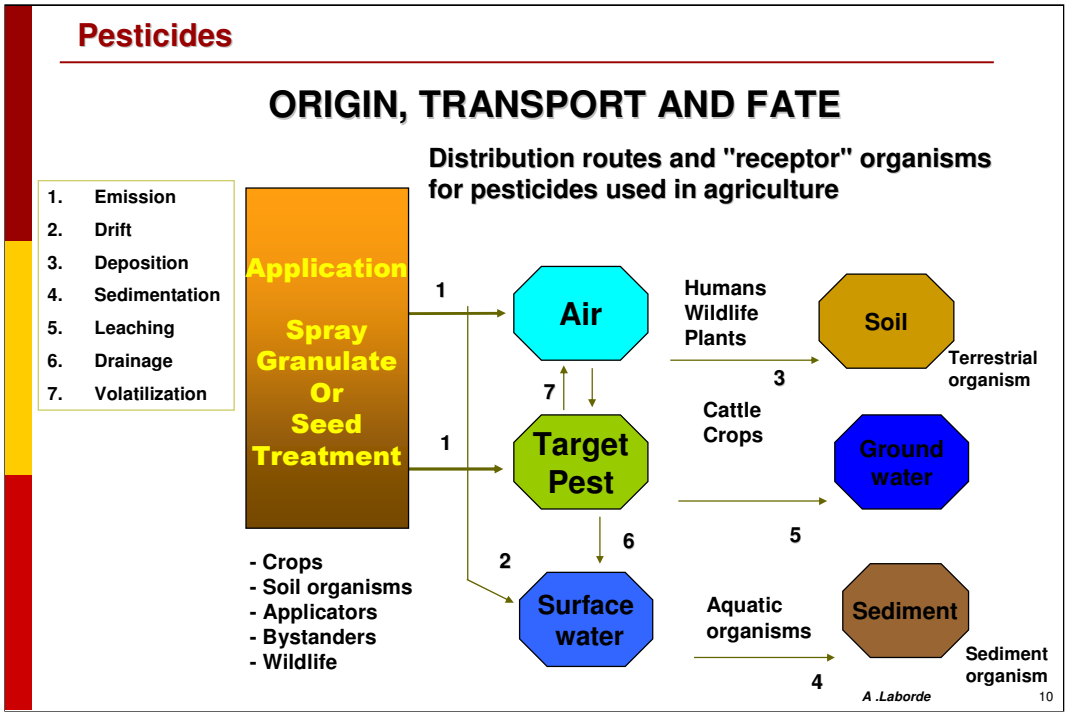
Exposure or emission into the environment can occur from on-site exposure through spraying or application of solid formulations to different targets. For example exposure can occur in children during:

- agricultural use (spraying fields) or seed treatment;
- use in cattle dips and in animal husbandry;
- use as household insecticide (indoor), or in gardens;
- sanitary indoor use in schools, offices, hospitals and other institutions;
- public health use (outdoor or indoor): in parks and urban areas and for vector control (e.g. malaria, Chagas disease, dengue and onchocercasis);
- medical human use: to treat head lice or scabies; and
- veterinary products for pets (e.g. to treat infestations with fleas or ticks).

Refs:

•IPCS. *The WHO recommended classification of pesticides by hazard. Guidelines to Classification 2000-2002* (www.inchem.org/documents/pds/pdsother/class.pdf).

•Tomlin C. *The pesticide Manual, 12th ed.* British Crop Protection Council Publications, 2000.



Pesticides have different distribution and persistence patterns in the environment, even if all of them are distributed in some way through air, soil and water. This should be addressed to gain an understanding of how acute and chronic exposure may occur because air, water and soil are the media of exposure.

This scheme illustrates the routes followed by an agricultural chemical (spray, granulate or seed treatment) that is applied to a given site, representing a risk to applicators, bystanders and wildlife.

When a pesticide is applied directly to a target pest (plant or animal) the whole site is affected including crop plants, soil organisms and, potentially, humans and wildlife in the immediate area. In addition, part of it goes to the air or to surface waters, due to emission (1) or drift (2). Once on the target site, the pesticide may "drain" (6) into surface waters or volatilize (7) into the air. From the air it may deposit (3) on humans, wildlife or plants or on the soil. From the animals or plants where it was applied the pesticide may leak (5) into groundwater.

Pesticides in surface water may go into aquatic organisms, and by sedimentation (4) into other organisms that remain in the sediment.

The persistence of the pesticide depends on its physical and chemical properties (partition coefficients, degradation rates, deposition rates) and the characteristics of the environment.

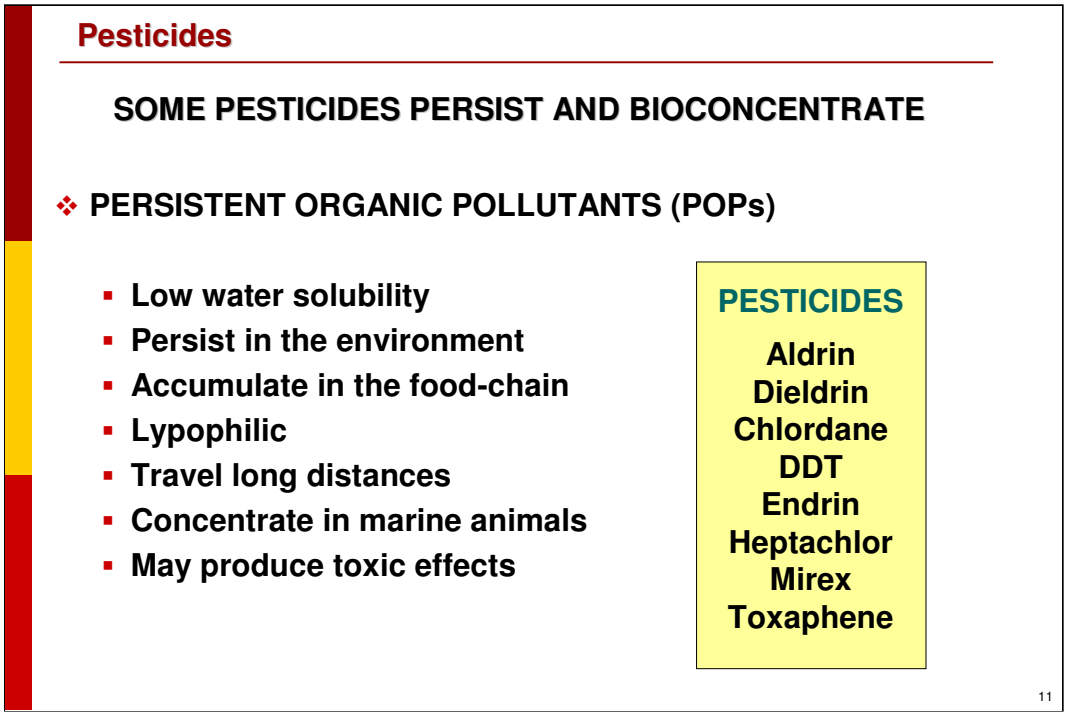
Climate characteristics also play a role in persistence. Studies in the Arctic have shown that insecticides and herbicides persist 3 to 8 times longer in cold climates than in temperate ones.

The most persistent pesticides are termed “persistent organic pollutants” (POPs) and are addressed in a separate module.

Refs:

•*Children: a CICH profile, 3rd ed.* Canadian Institute of Child Health, 2000.

•Health Canada. *Health and the environment: handbook for health professionals.* Ottawa, Ministry of Public Work and Government Services,1998.



Some pesticides are characterized by being very persistent in the environment. They may represent long-term dangers as they biomagnify up the food-chain. Humans, and particularly breastfed babies, are at the top of the food-chain.

•Most POPs (persistent organic pollutants) (these will soon be considered as persistent toxic substances or PTS) are organochlorine pesticides, namely, aldrin, endrin, clordane, DDT, heptachlor, mirex, toxaphene and hexachlorobenzene.

•They have been banned for agricultural or domestic uses in Europe, North America and many countries of South America in accordance with the Stockholm Convention (ratified in 2004). However, some organochlorine pesticides are still used – e.g. DDT is used to control malaria in some developing countries.

•Other POPs (and PTSs) include industrial chemicals (PCBs, HCB) and unintended byproducts (dibenzodioxins, dibenzofurans), and other chemicals.

•These persistent chemicals are controlled under the Stockholm Convention.

•POPs and PTSs are typically lypophilic compounds, with low water solubility, that are resistant to environmental breakdown and accumulate in adipose tissue.

•They bio-concentrate in fish, wildlife and human tissues.

•The highest levels are found in marine mammals.

•There is concern about potential endocrine and developmental effects of the POPs and PTSs, especially in children.

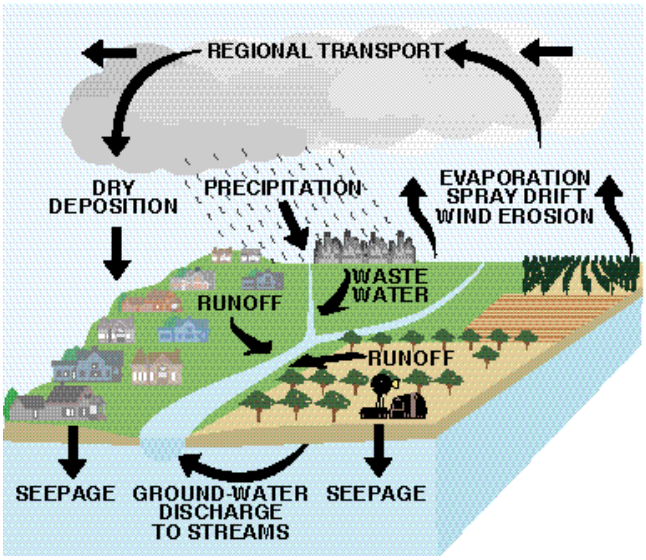
Pesticides

PESTICIDES IN THE ATMOSPHERE AND WATER



USGS

12

The US Geological Survey (USGS) monitors ground and surface water for 76 pesticides and seven pesticide breakdown products. A recent survey found that 90% of streams and 50% of wells tested were positive for at least one pesticide.

Ref:

•USGS: ca.water.usgs.gov/pnsp/index.html

A great potential for adverse effects of pesticides is through contamination of the hydrological system, which supports human life, aquatic life and related food-chains.

Pesticides

CHILDREN'S EXPOSURE

A cause of concern

- Multiple chemicals
- Multiple sources of exposure
- Multiple routes of exposure
- Multiple effects

WHO

15

Pesticides are considered an important environmental threat to children's health in rural areas. This is because:

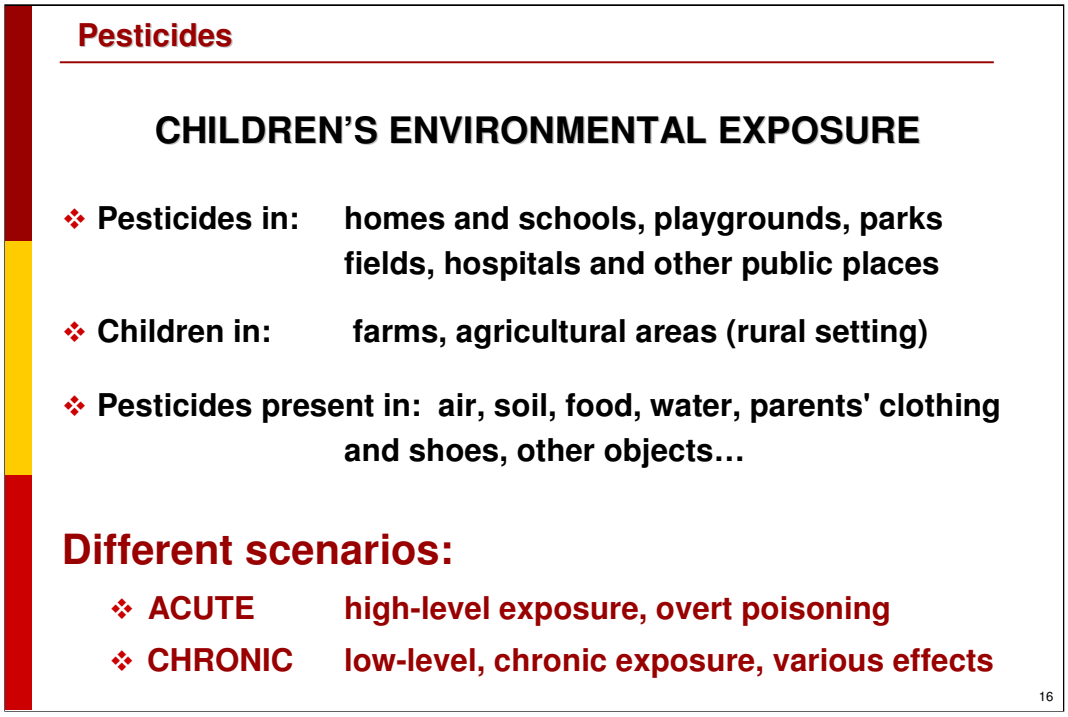
• A large variety of chemicals and mixtures are used as pesticides.

•Many pesticides are used at the same time in the same place (agricultural regions).

•They are ubiquitous in the environment – and in individual environments (micro-environments) of children – there may be several sources of exposure to the same or a different chemical.

•Multiple exposures may occur from the preconception period throughout the child's growth into adolescence and adulthood.

Pesticides may also be heavily used indoors in urban areas, so this is not solely a rural issue.



Children are exposed in different settings and by a variety of routes.

•Pesticides may be unsafely used in the home, by parents who want to protect their children from mosquitoes, cockroaches or rodents. Different pesticides may be stored within the reach of children. They are used in schools and playgrounds (in treated wood) and in green areas (parks and playing fields) to destroy weeds. Hospitals are intended to be places of healing, yet many are using hazardous pesticides

•Living on farms or in agricultural areas, where pesticides are frequently and heavily used, is a high-risk scenario for exposure.

•Potential for "take home" of pesticides on parents' clothing or shoes.

•Pesticides may be present in food and water, either as residues from treatment of crops or at higher levels, as a result of contamination.

•In some areas, there is a potential for release into the environment during production and formulation of pesticides (in factories).

•These are the circumstances under which children may receive **acute and high-level exposure leading to poisoning** or **chronic, low-level exposures** linked to more subtle, developmental and other effects. (See next slide)

Pesticides

SOURCES AND SETTINGS OF EXPOSURE...

HOME, SCHOOL, DAY-CARE, INSTITUTIONS, ...

WHO

Indoor and outdoor application

- Mosquito control
- Professional/domestic application

Health uses

- Lice or scabies
- Fleas or ticks on pets

Pesticide residues

- Dust, soil, furniture, carpets, toys, food…
- Playgrounds, playing fields, lawns, gardens
- Wood preservatives in play structures (e.g. PCP: pentachlorophenol)
- Long range transport of POPs (e.g. DDT)

17

A survey by the U.S. Environmental Protection Agency regarding pesticides used in and around the home revealed some significant findings:

•Almost half (47%) of all households with children under the age of five had at least one pesticide stored in an unlocked cabinet, less than 4 feet off the ground (i.e., within the reach of children).

•Approximately 75% of households without children under the age of five also stored pesticides in an unlocked cabinet, less than 4 feet off the ground (i.e., within the reach of children). This number is especially significant because 13% of all pesticide poisoning incidents occur in homes other than the child's home.

Pesticide application

•Professional application of pesticides both indoors and outdoors is used increasingly commonly for the control of rodents, cockroaches, ants, termites, earwigs and other pests. Signs and symptoms of pesticide-related-illnesses have been described after indoor and outdoor spraying.

•Domestic use of insecticides is also a source of exposure. Insecticides formulated as sprays, strips and baits are widely available.

•Certain topical pharmaceuticals for direct application on children's skin or scalp contain insecticides to control lice or scabies. Their use carries a risk of acute (chronic if repeated) overexposure. High doses or applications lasting a long time have caused acute poisoning. There are many pharmaceuticals described in the *International pharmacopoeia* that contain organophosphorus (malathion) and organochlorine (lindane) pesticides still being used to treat head lice. Such products may contains up to 2% of pesticide.

•Dogs and cats are often treated with insecticides to control fleas or ticks. Veterinary products can be as concentrated as agricultural ones. Pet dips for treatment of flea infestations usually contain organophosphate and pyrethroid pesticides. Children are often involved in pet care.

Pesticide residues

•Insecticides may persist in house dust, in soil tracked in from outdoors, in carpets, toys, food and furniture.

•High levels of insecticides have been measured for weeks after professional application.

•Residues of organophosphorus insecticides sprayed in indoor environments have been reported to occur on floors, carpets, children's toys, furniture, bed covers and in dust.

•Poor hygiene habits or houses that are difficult to clean increase the risk of exposure.

•Playgrounds, playing fields, lawns and gardens may be routinely sprayed in order to keep insects away.

•Pesticides are found in recreational waters (lakes, rivers and in pools (algaecides)).

•Persistent wood preservatives such as arsenic/ copper/chromium mixtures have been used on play structures.

•The persistent organic pollutants (POPs) include nine pesticides.

Pesticides

SOURCES AND SETTINGS OF EXPOSURE

Children living on farms or in agricultural areas are exposed to:

- **pesticide drift from sprayed fields**
- **contaminated dust & soil**
- **contaminated equipment and clothes**
- **treated fields**
- **parents spraying**
- **animal dips**
- **child labour**

Corra

19

The rural setting is of particular importance for children and young adults.

Children may be exposed to pesticide drift from fields that are being sprayed.

Acute “unintentional" poisoning, is possible when small children play with pesticide bottles and colourful containers that have been discarded in their playing areas.

Highly concentrated pesticides may be stored in rural homes.

Parents who are farm-workers or applicators may bring pesticides into the home through contaminated clothes, shoes or equipment.

Children may accompany their parents to the fields and help them with their tasks.

Infants who are still being breastfed are often carried by their mothers in the fields.

Children may help with agricultural tasks or may be allowed to play around the sprayed field.

Re-entry intervals (the time required before it is safe to return to a treated area) are not always respected or may be established on the basis of criteria that ensure adult safety only.

Concern is increasing about child labour and young workers.

Although few data are available, it is generally assumed that children make up a substantial part of the agricultural workforce in developing countries. They could be at a higher risk because they are less experienced and assertive than adults; they may lack protective equipment and receive less training or none at all.

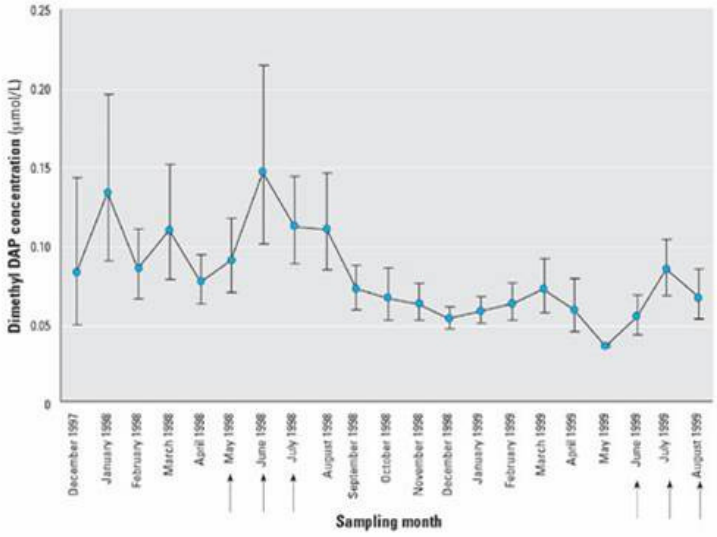
Pesticides

CHILDREN'S EXPOSURE IN RURAL SETTINGS

Increase in the levels of organo-phosphorus (OP) metabolites (DAP) paralleling pesticide spraying in a rural area



Koch *EHP*, 2002, 110 (8): 829

20

Numerous studies on children's exposure have demonstrated the absorption of pesticides.

Pesticide metabolites are used as biomarkers of exposure, and children often have higher levels than adults.

Younger children may have higher levels than older ones.

Levels of pesticides were associated with residence in rural areas AND with domestic use of pesticides.

The figure shows levels of dialkylphosphates (DAP) in children living in agricultural areas. Levels were measured in many samples taken over 1 year and were found to increase in parallel with periods of pesticide application.

Refs:

•Aprea C et al. Biologic monitoring of exposure to organophosphorus pesticides in 195 Italian children. *Env Health Perspect* , 2000, 108:521.

•Koch D et al. Temporal association of children's pesticide exposure and agricultural spraying: report of a longitudinal biological monitoring study. *Env Health Perspect,* 2002, 110:829.

We measured organophosphorus (OP) pesticide exposures of young children living in an agricultural community over an entire year and evaluated the impact of agricultural spraying on exposure. We also examined the roles of age, sex, parental occupation, and residential proximity to fields. We recruited 44 children (2–5 years old) through a Women, Infants, and Children clinic. We collected urine samples on a biweekly basis over a 21-month period. Each child provided at least 16 urine samples, and most provided 26. We analysed samples for the dialkylphosphate (DAP) metabolites common to the OP pesticides. DAP concentrations were elevated in months when OP pesticides were sprayed in the region's orchards. The geometric means of dimethyl and diethyl DAPs during spray months were higher than those during nonspray months (p = 0.009 for dimethyl; p = 0.018 for diethyl). Dimethyl DAP geometric means were 0.1 and 0.07 micro mol/L for spray months and nonspray months, respectively (57% difference); diethyl DAP geometric means were 0.49 and 0.35, respectively (40% difference). We also observed differences for sex of the child, with male levels higher than female levels (p = 0.005 for dimethyl; p = 0.046 for diethyl). We observed no differences due to age, parental occupation, or residential proximity to fields. This study reports for the first time the temporal pattern of pesticide exposures over the course of a full year and indicates that pesticide spraying in an agricultural region can increase children's exposure in the absence of parental work contact with pesticides or residential proximity to pesticide-treated farmland.

•Loewenherz C et al. Biological monitoring of organophosphorus pesticide exposure among children of agricultural workers in Central Washington State. *Environ Health Persp* 1997, 105:1344.

PESTICIDES IN DIFFERENT MEDIA

Air

- Respirable particles contaminated with pesticides
- Respirable aerosols during spraying
- Vapour from volatile residues of pesticides

Soil

- Hand-to-mouth behaviour
- Crawling on the ground
- Dermal contact

Some pesticides are volatile and can be inhaled over a period of hours or days because of the volatilization from contaminated surfaces.

Particulate material under 10 micrometres is breathable, and the smaller particles are more dangerous because they can reach the alveoli. Children can be exposed when they are around the spraying area.

The persistence of pesticides in the soil depends on their chemical characteristics and many pesticides used in homes have been found, many days to weeks after the application, in house dust.

The behaviour of children (e.g. crawling and hand-to-mouth activities) facilitates exposure.

PESTICIDES IN DIFFERENT MEDIA

Water

- **Pesticides in drinking water: tap, well**

Food

- **Crops routinely sprayed:**
  - **fruits, vegetables, grains**
- **Bioaccumulation in animals and products**
  - **fish, meat, eggs, dairy**

WHO

Once used or spilled, pesticides may contaminate the water used for drinking or bathing.

Pesticides can contaminate nearby groundwater and surface water.

There is increasing concern about dietary ingestion of pesticide residues by children, in both plant and animal products. Please note that the benefits to children of a diet rich in fruits and vegetables should be emphasized. There are preventive and regulatory measures on this issue. (See additional slides)

Picture: WHO, C. Gaggero. Nutrition child, Peru.

<<READ SLIDE.>>

PESTICIDES IN DIFFERENT MEDIA

Food residues

- Many food products have detectable levels of pesticides
- Guideline levels of pesticides in food (MRL)
- Guidelines to limit the population exposure: acceptable daily intake (ADI)

WHO 23

All industrialized countries have food monitoring programmes that measure pesticide residues.

Levels exceeding the maximum established limits have been reported occasionally in monitored food.

Maximum limits for residues have been established only for certain pesticides.

Although a single pesticide may be considered safe at a particular level, foods may contain residues of several pesticides at the same time (see the next slide for an example of the pesticide application scheme in apple trees) and to understand the effect of multiple exposures.

Locally grown food may not be properly monitored or controlled for residues of pesticides.

Families who eat food directly brought in from fields may have higher pesticide exposure.

A study of cumulative dietary pesticide intake in children from an agricultural community showed that up to 56% of the children exceeded the acceptable chronic dietary doses *(Fenske, 2000)*.

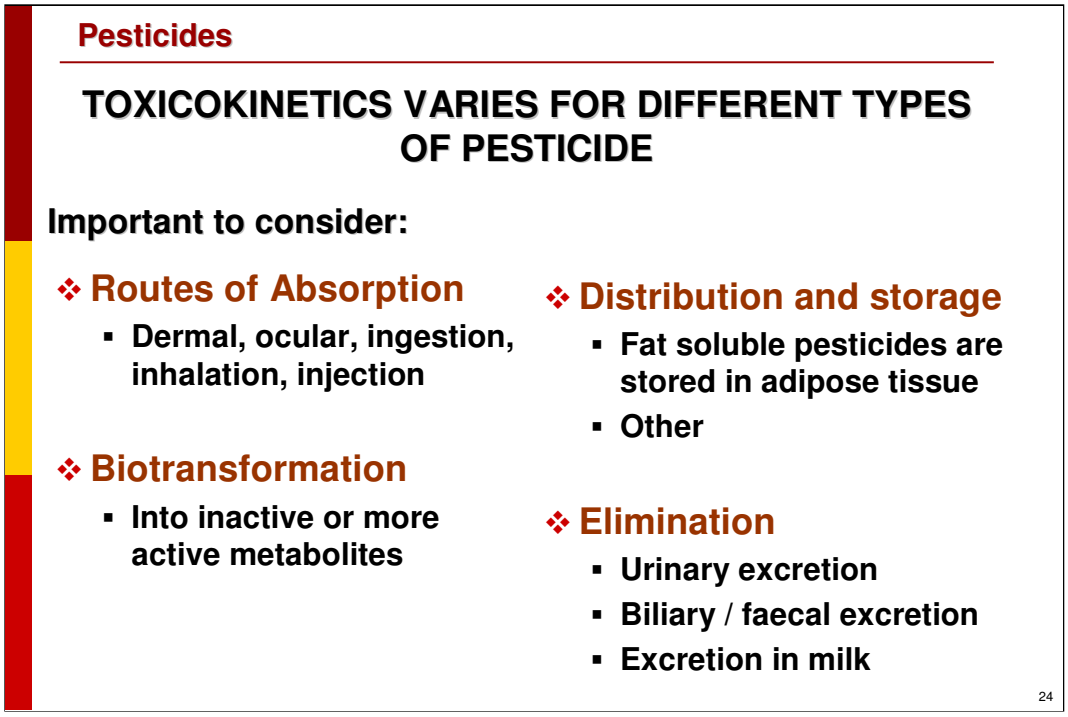
Picture: WHO (L. Taylor), Nutrition, 1994



Toxicokinetics depend on the specific pesticide, its chemical characteristics and formulation.

Routes of absorption are explained in the following slides.

•The biotransformation of most pesticides involves a combination of several chemical reactions including oxidation, reduction, hydrolysis and/or conjugation, producing different metabolites that may be more or less active (toxic).

• Biotransformation of some organophosphate pesticides involves oxidative activation (e.g. parathion = paraoxon).

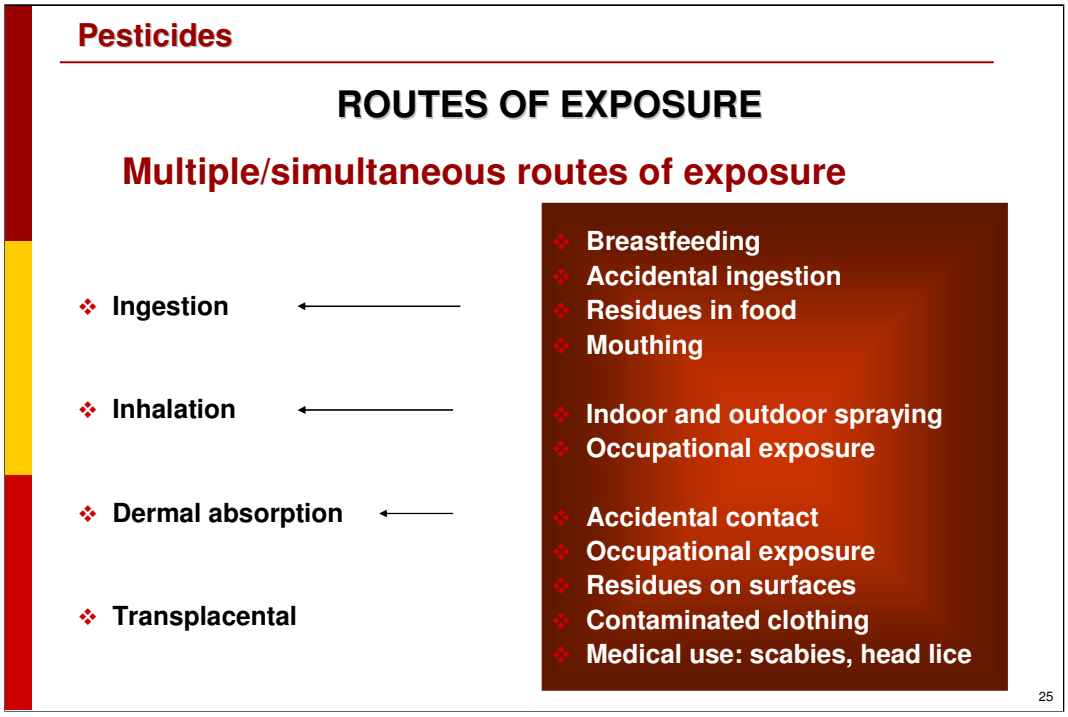
•Pesticides may reach different organs and tissues. Many pesticides accumulate in the adipose tissues.

•Elimination is urinary, biliary and faecal.

•Excretion in milk has been experimentally found to be proportional to blood dosage for DDT, dieldrin, aldrin, heptachlor and other organochlorine pesticides.

Ref:

•Hodgson. Metabolism. In: *Hayes, Handbook of pesticide toxicology*. San Diego California, Academic Press Inc. 1991.



Almost all pesticides are absorbed by these routes.

<<READ SLIDE.>>

Different routes are associated with different settings and media of exposure. However, there are settings in which more than one route of exposure can occur (e.g. in an occupational setting).

Pesticides can cross the epithelium of the skin and mucous membranes that exchange gases (alveoli) or nutrients (gastrointestinal mucosa).

The rate of absorption depends on the chemical properties, amount of the chemical, length of exposure and the physical state of the molecule. There are also other factors that may contribute to increased absorption. Skin absorption is higher when there is vasodilatation (e.g. in summer, or with heating). Respiratory absorption is many times higher when respiration is more rapid (e.g. when playing or running).

(Transplacental exposure is considered in the next slide.)

In relation to their body weight, children have a larger skin area than adults, breathe in more air and drink and eat more. These aspects and certain childhood behaviours such as putting fingers and objects in their mouths allow exposure to larger amounts of pesticide per kilogram of body weight. Modifying diets and assuming their variety could be a way of reducing exposures...

Pesticides

ROUTES OF PERINATAL EXPOSURE

- **Mother's intake and body burden is transferred across the placenta**
- **Breast milk may be contaminated**
  "The very top of the food chain"

WHO 26

Pesticides can cross the placenta:

•They have been detected in the amniotic fluid and body tissues of human foetuses even during early stages of prenatal life.

•Pesticides have also been found in the meconium.

•Measuring organophosphate compounds (OP) metabolites in meconium is considered a good biomarker of prenatal exposure because meconium starts to accumulate in the 16th week of pregnancy and is eliminated following delivery.

Breast milk may be contaminated and represents the very top of the food-chain:

•Residues of organochlorine pesticides and POPs have been detected in breast milk (including DDT, HCB and HCH isomers) in contaminated areas.

•There is currently no developed method to measure OPs in breast milk.

(Please see the module on Children and Chemicals.)

Pesticides

METABOLIC PATHWAYS

- **Organophosphates metabolize into:**
  - **Oxones**
  - **Specific inactive metabolites (ME)**
  - **Non-specific metabolites: dialkylphosphates (DAPs)**

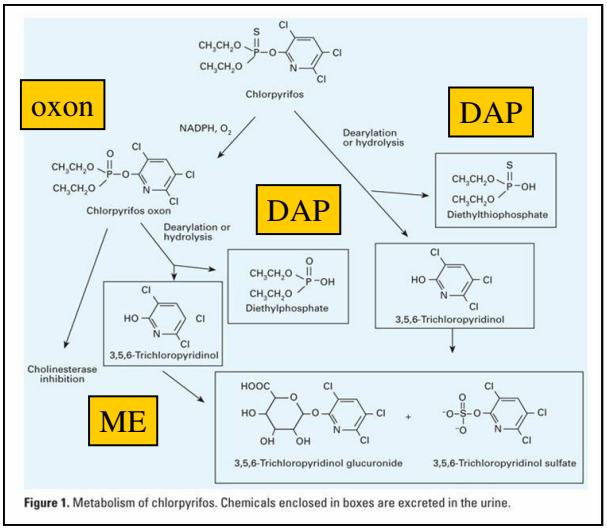

Figure 1. Metabolism of chlorpyrifos. Chemicals enclosed in boxes are excreted in the urine.

Wessels, EHP (2003) 111 (16): 1939

27

Metabolism may either activate or inactivate the chemical.

Therefore, immature metabolic pathways may be protective or increase the danger from specific chemicals.

As an example, organophosphates are metabolized to oxones (active metabolite), but also to other specific inactive metabolites (ME) and to non-specific metabolites (the dialkylphosphates (DAPs)) (shown in the figure).

DAPs are used as biomarkers of environmental exposure to all kinds of organophosphate pesticides because DAPs are metabolites of all these pesticides.

Ref:

•Wessels D et al. Use of biomarkers to indicate exposure of children to organophosphate pesticides: implications for a longitudinal study of children's environmental health. *Environmental Health Perspectives*, 2003, 111:1939.

Figure: Reproduced with permission from Environmental Health Perspectives

MECHANISMS OF ACUTE TOXICITY

- Irritation (most of the pesticides)
- Allergic sensitization (e.g. fungicides)
- Enzyme inhibition (e.g. cholinesterases and OPs & carbamates)
- Oxidative damage (e.g. paraquat)
- Inhibition of neurotransmission (e.g. organochlorines)
  - Calcium (Ca^{2+}) homeostasis alteration
  - GABA inhibition
- Uncoupling of oxidative phosphorylation (e.g. glyphosate)

Several mechanisms of toxicity have been described and these differ according to the specific properties of the pesticide. They are summarized below.

•Irritation is a local effect due to contact of the pesticide with the skin, eyes or other mucosa.

- The effects are usually redness and pain.

- Respiratory irritation can produce nasal, laryngeal or pulmonary effects.

- Most herbicides and fungicides are strong irritants.

•Allergic sensitization is a common effect of pesticides, especially fungicides.

•Enzyme inhibition (e.g. cholinesterase activity is decreased by exposure to organophosphorus compounds and carbamates).

•Oxidative damage (e.g. paraquat is a promoter of superoxide radicals).

•Inhibition of neurotransmission (organochlorines inhibit the GABA system and cause alteration of calcium homeostasis.

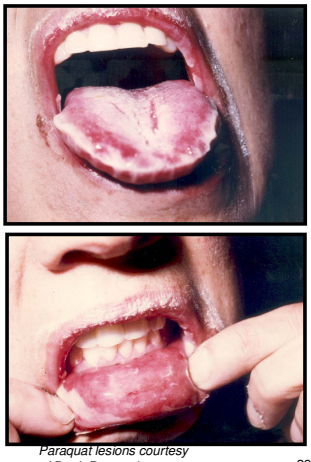
•Uncoupling of oxidative phosphorylation (e.g. glyphosate).

OP: organophosphorus compounds

Pesticides

ACUTE PESTICIDE-RELATED ILLNESS

- Dermal and ocular irritation (or allergic response)
- Upper and lower respiratory tract irritation
- Allergic responses / asthma (fungicides)
- Gastrointestinal symptoms
- Neurological symptoms
- Specific syndromes
  - Cholinergic crisis (organophosphorus pesticides)
  - Bleeding (warfarin-based rodenticides)
  - Caustic lesions and pulmonary fibrosis (herbicide, paraquat)



Paraquat lesions courtesy of Dr. J Pronczuk

29

The signs and symptoms of pesticide poisoning depend upon the pesticide involved and the type and magnitude of exposure.

In general the signs and symptoms are:

•dermal and ocular irritation (or allergic response)

•upper and lower respiratory tract irritation

•allergic responses and asthma

•gastrointestinal symptoms: usually vomiting, diarrhoea and abdominal pain

•neurological symptoms: excitatory signs in the case of exposure to organochlorines, lethargy and coma; also polyneuritis

•specific syndromes:

- cholinergic crisis (organophosphorus pesticides)

- bleeding (warfarin-based rodenticides)

- caustic lesions and pulmonary fibrosis (paraquat)

<<NOTE TO USER: Refer to those pesticides commonly used in the country/area.>>

<<NOTE TO USER: insert local photo.>>

Pesticides

ACUTE POISONING BY "ACCIDENTAL" INGESTION

- **Storage of leftover pesticide in a medicine or soft drink bottle**
- **Confusion with pharmaceutical**
- **Pesticide container reused for storing drinks or food**
- **Pesticide container present in the child's environment**

Bottles containing pharmaceuticals and the pesticide chlorpyriphos
Laborde, CIAT, Montevideo

30

Acute poisoning results from "accidental" (non-intentional) exposure in toddlers and small children.

Ingestion occurs, for example, when:

•Pesticides have been stored in a medicine or soft drink bottle.

•The pesticide bottle is similar to a bottle used for pharmaceuticals.

•Pesticide containers are reused for storing drinks or food.

•Pesticide containers are easily accessible in the child's environment.

Pesticides

DIAGNOSIS OF EXPOSURE

- **History of exposure**
  - **Availability of pesticides**
  - **Recent application**
- **Signs and symptoms**
  - **May be misdiagnosed!**
- **Laboratory tests**

WHO

31

<<READ SLIDE.>>

The diagnosis is based upon the history of exposure (e.g. pesticides are available in the home, recently applied, or child was found playing with containers), signs and symptoms of exposure (see next slides) and laboratory measurements. Diagnosis also requires a high index of suspicion. Even after acute exposures, pesticide poisoning may be misdiagnosed as a viral illness (e.g. infectious diarrhoea rather than organophosphate poisoning) resulting in inadequate treatment and potentially returning children to a setting where exposure will be ongoing or recur.

Pesticides and/or their metabolites can be measured in samples of blood, urine, breast milk, amniotic fluid or meconium. This can confirm the diagnosis.

Laboratory tests are available to assess exposure to organophosphates, organochlorine, dicarboximide fungicides, carbamates, dipyridyl herbicides (e.g. paraquat) and pyrethroids.

Pesticides

LOW-LEVEL CHRONIC EXPOSURE

Growing body of epidemiologic and animal data and research studies suggests a link between long-term exposure and:

- **Abnormal growth and development**
- **Impaired neurobehavioral development / functions**
- **Cancer**
- **Increased susceptibility to infections**

35

The mechanisms of action thought to produce chronic toxic effects include genotoxicity, endocrine disruption and immunotoxicity.

Effects may be seen when exposure occurs during critical windows of development, particularly the prenatal period. See additional slides.

Pesticides

PRECONCEPTIONAL PRENATAL EXPOSURE

Pesticide exposure before or during pregnancy has been associated with increased risk of:

- **Infertility**
- **Perinatal death**
- **Spontaneous abortion**
- **Premature birth**
- **Fetal growth retardation**
- **Congenital malformations**
- **Early childhood cancer**

WHO 36

Exposure of either **mother** or **father** to pesticide before conception, or exposure of the mother during pregnancy, has been associated with an increased risk of fetal death, spontaneous abortion and early childhood cancer.

There is increasing evidence that *in utero* exposure increases the risk of growth retardation: a small-for-gestational age baby, low birth weight, reduced length and small head circumference (see photo).

Significant increases in the risk of congenital anomalies have also been reported. These include**:** eye defects, limb reduction, urogenital defects, hypospadias, cryptorchidism, orofacial clefts, central nervous system defects and heart defects.

Exposure during brain growth may exert subtle, permanent effects on the structure and function of the brain. These include:

•neuronal and axonal differentiation;

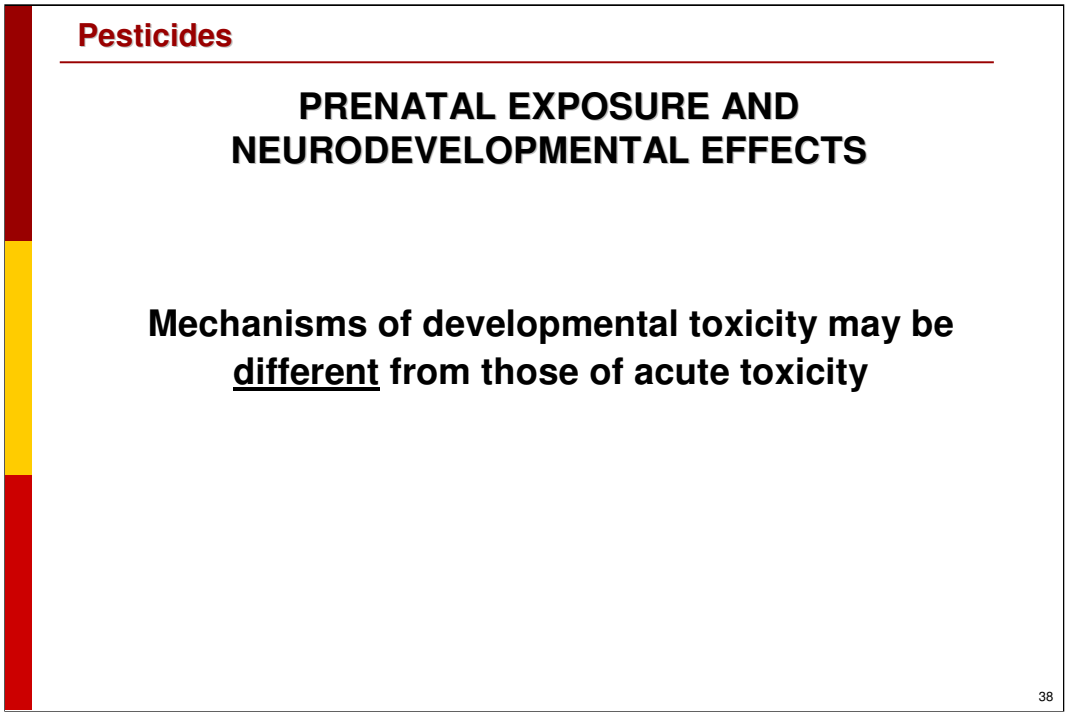
•alteration of serotoninergic system; and

•altered synaptogenesis and programming of synaptic function.

Ref:

•Slotkin TA. Guidelines for developmental neurotoxicity and their impact on organophosphate pesticides: a personal view from an academic perspective, Neurotoxicology, 2004, 25:631.

The appropriate regulation of drugs, chemicals and environmental contaminants requires the establishment of clear and accepted guidelines for developmental neurotoxicity. Ideally, these guidelines should encompass the ability to assess widely disparate classes of compounds through routine tests, with high throughput and low cost. Increasingly, however, the progress in primary research from academic laboratories deviates from this goal, focusing instead on categorizing novel effects of toxicants, development of new testing paradigms, and extension of techniques into molecular biology. The differing objectives of academic science as opposed to those of regulatory agencies or industry, are driven in part, by the priorities of the agencies that fund primary research. Recent work on organophosphate pesticides (OPs) such as chlorpyrifos (CPF) illustrate this dichotomy. Originally, OPs were thought to affect brain development through their ability to elicit cholinesterase inhibition and consequent cholinergic hyperstimulation. This common mechanism allowed for parallels to be drawn between standard measures of systemic toxicity, gross morphological examinations, and exposure testing utilizing an easily-assessed surrogate end-point, plasma cholinesterase activity. In the past decade, however, it has become increasingly evident that CPF, and probably other OPs, have direct effects on cellular processes that are unique to brain development, and that these effects are mechanistically unrelated to inhibition of cholinesterase. The identification and pursuit of these mechanisms and their consequences for brain development represent new and exciting scientific findings, while at the same obscuring the ability to sustain a uniform approach to neurotoxicity guidelines or biomarkers of exposure. In the future, a new set of test paradigms, relying on primary work in cell culture, invertebrates, or non-mammalian models, followed by more targeted examinations of specific processes in mammalian models, may unite cutting-edge academic research with the need for establishing flexible guidelines for developmental neurotoxicity.



Acetylcholinesterases are enzymes that play a direct role in axonal outgrowth and neuronal differentiation. Exposure to organophosphorus pesticides inhibits the enzymes and may therefore interfere with this function. The pesticides chlorpyrifos and diazinon alter axonogenesis, synaptogenesis and programming of synaptic functions. The mechanisms of action postulated are: serotonergic system alteration and inhibition of RNA synthesis in neurones and glial cells. Data suggest that some of the toxicity is from the parent compound rather than the active metabolite and occurs independently of the cholinergic systems that are responsible for acute toxicity.

And, these neurodevelopmental toxicities occur at exposure levels too low to cause overt symptoms of cholinesterase inhibition in the pregnant animals.

Pesticides

CHRONIC NEUROLOGICAL EFFECTS

- **Neurological sequelae of acute poisoning**
- **Neurological symptoms due to high indoor levels of pesticides**
- **Subtle changes in memory and attention**

39

It may be difficult to differentiate the effects of prenatal exposure from exposure in early childhood, or sequelae of non-fatal acute poisonings.

Chronic neurobehavioural and neurological effects after acute poisoning with organophosphorus pesticides have been reported in adults.

Memory and concentration problems, unusual fatigue, irritability and depression, visual difficulties and delayed polyneuropathy have been described.

In a well-documented case of chronic organophosphorus pesticide poisoning, the house of an infant with hypertonia, first diagnosed as cerebral palsy, was found to have high levels of chlorpyrifos weeks after a professional application (*Wagner, 1994*).

Few studies have examined the neurobehavioural effects of postnatal exposure to pesticides.

Subtle changes in short-term memory and attention may be associated with application of organophosphorus pesticides in the home.

There is increasing evidence, particularly from animal models, about neurobehavioural effects of long-term exposure to low levels of pesticides.

PESTICIDES AND CHILDHOOD CANCER

Some studies have found an association between postnatal pesticide exposure and an increased risk of paediatric cancer

- **Brain tumours**
- **Acute lymphocytic leukaemia**
- **Non-Hodgkin lymphoma**

A number of epidemiologic studies have found a significant association between cancer and domestic exposure to pesticides.

Evidence is increasing, but still limited because of the methodological weaknesses of the research.

Investigations in children living in the rural areas of developed countries have also produced limited evidence.

Refs:

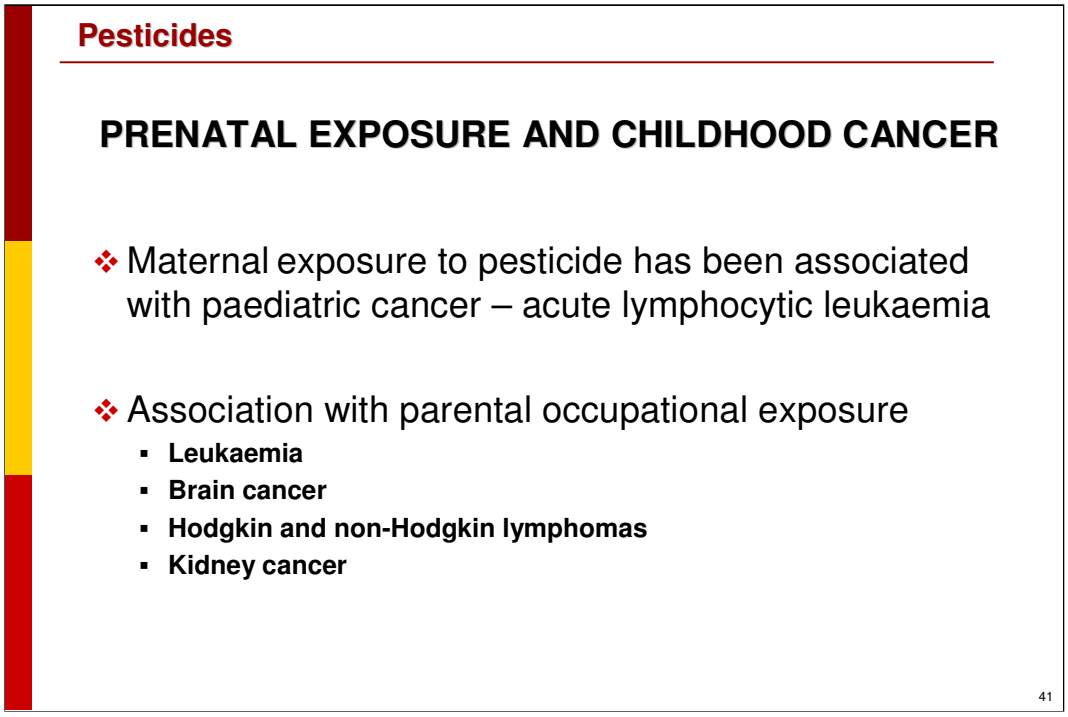
•Borkhardt A et al. Congenital leukaemia after heavy abuse of permethrin during pregnancy. *Arch Dis Child Fetal Neonatal Ed.* 2003, 88:F436.

•Daniels JL et al. Residential pesticide exposure and neuroblastoma. *Epidemiology,* 2001. 12:20.

•Leiss JK et al. Home pesticide use and childhood cancer: a case-control study. *Am J Public Health*, 1995, 85:249.

•Ma X et al. Critical windows of exposure to household pesticides and risk of childhood leukaemia. *Environ Health Perspect*, 2002, 110:955.

•Pogoda JM et al. Household pesticides and risk of pediatric brain tumors. *Environ Health Perspect,* 1997, 105:1214.



Prenatal exposure has been associated with leukaemia in a newborn after intensive use of permethrin at home by the pregnant mother. Children with certain metabolic enzyme polymorphisms have an increased risk of acute lymphocytic leukaemia when exposed to pesticides *in utero* or during pregnancy (particularly 2,4-D herbicide). Brain cancer appears to be associated to maternal exposure during agricultural activities. There are some controversial studies that suggest an increased risk of cancer in children whose parents had occupational exposure to pesticides.

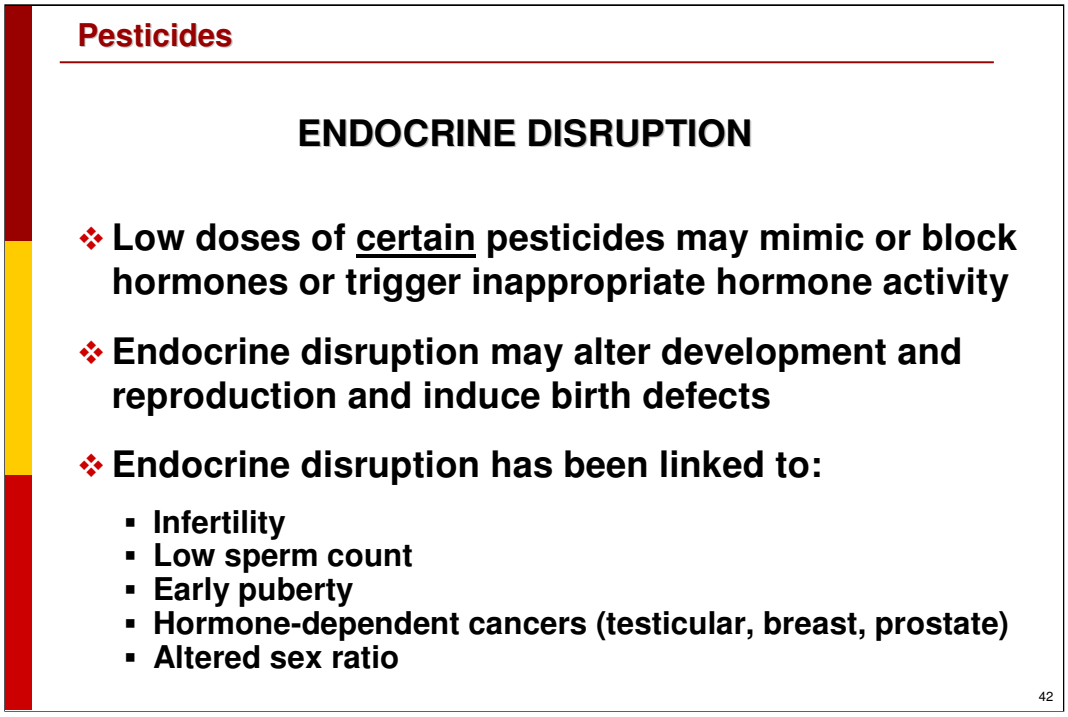
•Zahm SH et al. Pesticides and childhood cancer. *Environ Health Perspect*, 1998, 106:893.



Endocrine disruption is not an effect, but a *mechanism* of toxicity that may have different effects.

Evidence of the effect related to this mode of toxicity in children is still limited.

There is experimental evidence of endocrine disruption. Pesticides may have:

•estrogenic effects (DDT, dieldrin, endosulfan, methoxychlor)

•anti-androgenic effects (DDT, vinclozilin, procymidone)

•anti-thyroid effects (ethylenethiourea (ETU), maneb, zineb metabolites)

•anti-progestin effects (DDT).

Synthetic pesticides may interfere with the natural process of development.

Pesticides

IMMUNOTOXICITY

- **Immunotoxicity is suspected, but evidence is limited**

Studies in Arctic zone:

- **Higher incidence of ear infections**
- **Cytokine panel abnormalities**

www.smithsonianmag.si.edu/smithsonian/issues04/jan04/images/topdogs_mush_jpg.html

43

Evidence on the immunotoxic mode of action and effects is limited. Studies from the Arctic zone and Europe are beginning to provide some evidence. Children contaminated with chlordane and heptachlor had cytokine panel abnormalities.

Inuit infants from the Artic exposed *in utero* and to breast milk contaminated with *p,p´*-DDE, hexachlorobenzene and dieldrin had an elevated risk of otitis media.

This summary slide shows the complexity of the issues related to children's environmental exposure to pesticides and the effects on their health.

Pesticides used in agriculture, treatment of animals, on lawns ("cosmetic"), and for protection of human and public health may enter the air, food, water and soil in the places where children spend most of their time (e.g. at home, at school, in playgrounds, on farms and in fields) and may also contaminate their toys, floors, carpets and materials in their playgrounds.

Children become exposed by:

•eating and drinking contaminated food and beverages

•playing in contaminated areas

•gaining acces to unsafely stored pesticides, or pesticides stored in attractive, colourful containers

•helping in the house and on the farm or as child labour

•Contact with clothing or shoes of working parents

Children have special susceptibilities related to:

•paraoxonase (PON) - it catalyzes the hydrolysis of toxic metabolites and can protect against pesticide toxicity, which then depends on the PON genotypes

•critical windows of susceptibility

•age

•nutritional status

•poverty

Exposure may lead to:

•acute effects including irritation of the skin or eyes, coughing, lacrimation

•poisoning, with systemic effects

•neurotoxicity

•impaired development

•endocrine disruption

•cancer

Pesticides

OBSOLETE PESTICIDES

Obsolete pesticides are pesticides that can no longer be used for their intended purpose or any other purpose.

They may include:

- Pesticides in liquid, powder or dust, granule, emulsion form.
- Empty and contaminated pesticide containers
- Heavily contaminated soil
- Buried pesticides

Causes of obsolete pesticides:

- Use prohibited for health/environmental reasons
- Product deteriorated as result of improper or prolonged storage
- Product not suitable for intended use and cannot be used for other purposes, nor can it easily be modified to become usable.

Obsolete, unwanted and banned pesticides are serious environmental hazards. Leaking and corroding metal drums filled with obsolete and dangerous pesticides dot urban and rural landscapes of developing countries around the world. These chemical leftovers have become villains in the agricultural world they were designed to help, affecting not only a nation's agriculture and its environment, but also fundamentally the health of its people and consequently development in general be it in rural areas or under urban conditions.

This global environmental tragedy is a direct result of several decades of mishandling and misuse, but is most dramatic in the developing world where there is no awareness of the inherent danger of pesticides. The unaware therefore draw water from contaminated site for own survival and that of their animals.

Obsolete pesticides may include: **<<READ SLIDE>>**

Most of the affected countries are under tropical conditions where agricultural and vector pests flourish both in diversity and numbers. Migratory pests such as locusts, grasshoppers, grain eating birds, storage pests, rodents, etc. inflict untold damage to agriculture and bring about hunger or misery when they are at their peak.

Poor nations have been led to believe that the only alternative to combat pests agricultural or otherwise effectively is only by using pesticides. The poor or the unaware never think for a moment that pesticides are poisonous and that they are dangerous to life. Most believe that pesticides are like medicines. They consider that they kill pests selectively and are therefore less harmful to humans, animals and plants. Governments save budgets to purchase pesticides on regular basis. Also constantly plead to donors and organizations for assistance either for direct supply of pesticides or for contributions of financial support for purchasing them. In response, donors and organizations supply pesticides.

Recipient countries anxious to minimize pest damages to the minimum or, being less aware of the negative consequences, usually receive pesticides from every possible source and direction. This leads to uncoordinated influx of pesticide donations and trading, subsequently giving rise to excessive supply. While some of the donations are genuine, others take the opportunity to dump unwanted and illegal pesticides on the poor and unsuspecting countries. Pesticides reach individual farmers or household dwellers that value pesticides dearly. They keep them in their houses, with their food and animals. Pesticide vendors take the opportunity to promote pesticides aggressively. It is not uncommon to find pesticides being stored in the open or in heavily populated zones and usually in substandard stores and sold along with food and drinks, etc. Children are used in advertising sales of pesticides and often get easy access to pesticides.

They play with empty pesticide cans and use them for drinking water or milk. Most pesticide cans litter high streets or are simply dumped in open municipality dumps for subsequent open burning leading to serious emissions of dioxins.

Common causes of obsolete pesticides include the following:

•Use of the product has been prohibited or severely restricted for health or environmental reasons (e.g. through banning; withdrawal of registration, or policy decision by relevant government agencies)

•The product has deteriorated as a result of improper or prolonged storage and can no longer be used according to its label specifications and instructions for use, nor can it easily be reformulated to become usable again.

•The product is not suitable for its intended use and cannot be used for other purposes, nor can it easily be modified to become usable.

Other possible reasons for why we have obsolete pesticide include:

•Banning of pesticides that are still kept in store.

•Aggressive pesticide sales, promotions and distributions by the Chemical Industry.

•Difficulties in forecasting outbreaks of pest.

•Inappropriate assessment of pesticide requirements.

•Insufficient application capacity.

•Inappropriate formulations or substandard containers.

•Excessive donations: these are usually inappropriate because they are not received when needed most (i.e. late arrival of donations or out of season delivery), or are uncoordinated with similar donations from various sources. Such are tantamount to dumping.

•Inadequate storage facilities and lack of staff trained in storage management (i.e. poor stock taking and lack of records).

•Ineffective distribution or poor marketing systems for pesticides (government or private sector or both).

•Lack of awareness of the inherent dangers of pesticides.

•Misuse of pesticide containers (e.g. for a variety of domestic uses, water containers, food storage, use for pot plants, etc.).

Notes from FAO: www.fao.org/WAICENT/FAOINFO/AGRICULT/AGP/AGPP/Pesticid/Disposal/index_en.htm

OBSOLETE PESTICIDES

Disposal of obsolete pesticides:

- United Nations Food and Agriculture Organization has developed a set of guidelines for disposal.
- Contact your local authorities for advice on disposal.

FAO

Disposal of obsolete pesticides:

•In many countries, obsolete pesticides are a problem. The United Nations Food and Agriculture Organization have developed a set of guidelines for disposal, available at: *www.fao.org/WAICENT/FAOINFO/AGRICULT/AGP/AGPP/Pesticid/Disposal/index_en.htm*.

•Contact your local authorities for advice on disposal.

WHO Recommended Classification by Hazard contains a table of active ingredients (available at: www.inchem.org/documents/pds/pdsother/class.pdf) believed to be obsolete or discontinued for use as pesticides.

<< NOTE TO USER: Do you have stockpiles of obsolete pesticides in this country? If so, what is the reason for it?>>

Notes from FAO:
www.fao.org/WAICENT/FAOINFO/AGRICULT/AGP/AGPP/Pesticid/Disposal/index_en.htm

Picture: FAO, I. Balderi. Obsolete pesticides that have heavily leaked into the environment polluted and contaminated ground water and containers left from domestic use have disappeared into the soil.

Pesticides

PREVENTION OF EXPOSURE

What can be done to prevent pesticide exposure and poisoning ?

WHO

❖ **Take action at**

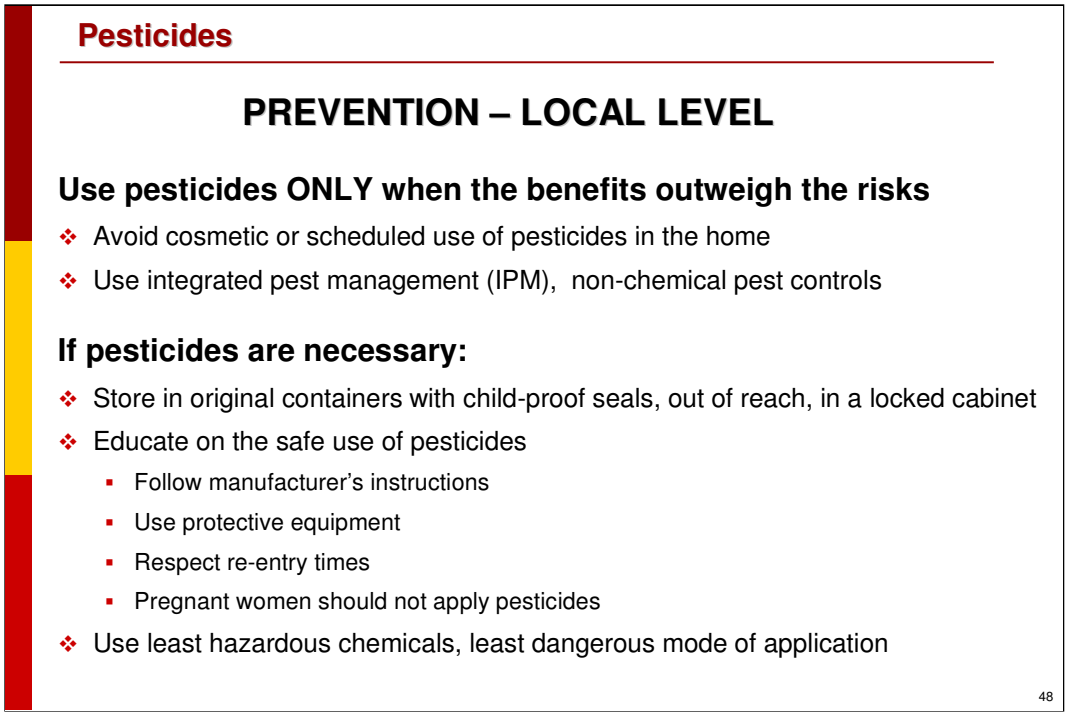
- **Local level**
- **National level**
- **International**

47

<<READ SLIDE.>>

Because of the potential for long-term damage to critical structures such as the nervous system, immune system and endocrine system, prevention of all acute poisoning events as well as of exposure to low doses during development is a high priority for ensuring children's environmental health. There are many steps that can be taken at the local/practice level, national/government level and international treaty/trade levels to decrease exposure to pesticides and related illnesses.

Picture: WHO, L. De Toledo. Ethiopia



Pesticides should be used only when the benefits outweigh the risks, and non-chemical pest control procedures have failed.

Cosmetic use of pesticides, that is their use to control aesthetically unpleasant plants or non-dangerous insects such as crickets or house millipedes, should be completely avoided.

Integrated pest management (IPM) procedures which include hygiene, sealing of cracks and crevices, screening of doors and windows, and other measures should be the first line of defence for pest management.

If pesticides must be used, they should be stored only in their original containers with manufacturer's labels intact, preferably with child-proof seals, out of the reach of children and in locked cabinets or cupboards.

Users should always follow the safety precautions specified by the manufacturer and observe all safety recommendations including use of gloves, masks, protective clothing and observation of re-entry times (the time when it is safe to return to a treated area).

Pregnant women should not apply pesticides and particular care should be taken to determine appropriate re-entry times for pregnant women, infants and small children. These times may be considerably longer than for less vulnerable individuals.

If chemicals are required, the least hazardous chemical (when there is scientific evidence of less toxicity) should be used with the most contained mode of distribution considered effective. For example, fogs and bombs should not be used. Bait stations are preferable to baseboard sprays or crack and crevice treatment. Granules and bait stations should be used only if they are inaccessible to babies, toddlers and small children (and pets).

Pesticides

PREVENTION – COMMUNITY LEVEL

- **Integrated pest management (IPM)**
  - **Homes**
  - **Schools**
  - **Public buildings**
  - **Health centres**
  - **Public parks**
- **Community activities**
  - **Community campaigns**
  - **School activities**
  - **Local awards or contests**
  - **Pesticide-free "zones"**
  - **Support organic farming**

WHO

49

Many organizations (especially FAO and WHO) promote alternative non-chemical forms of pest-control and there is increasing engagement in non-pesticide dependent agriculture and integrated pest management (IPM).

A variety of local initiatives involving the community can help to create an environment that promotes decreased dependence on pesticides in homes, schools, public areas, health facilities and parks.

Examples of community activities include:

•community campaigns and school activities

•local awards or contests

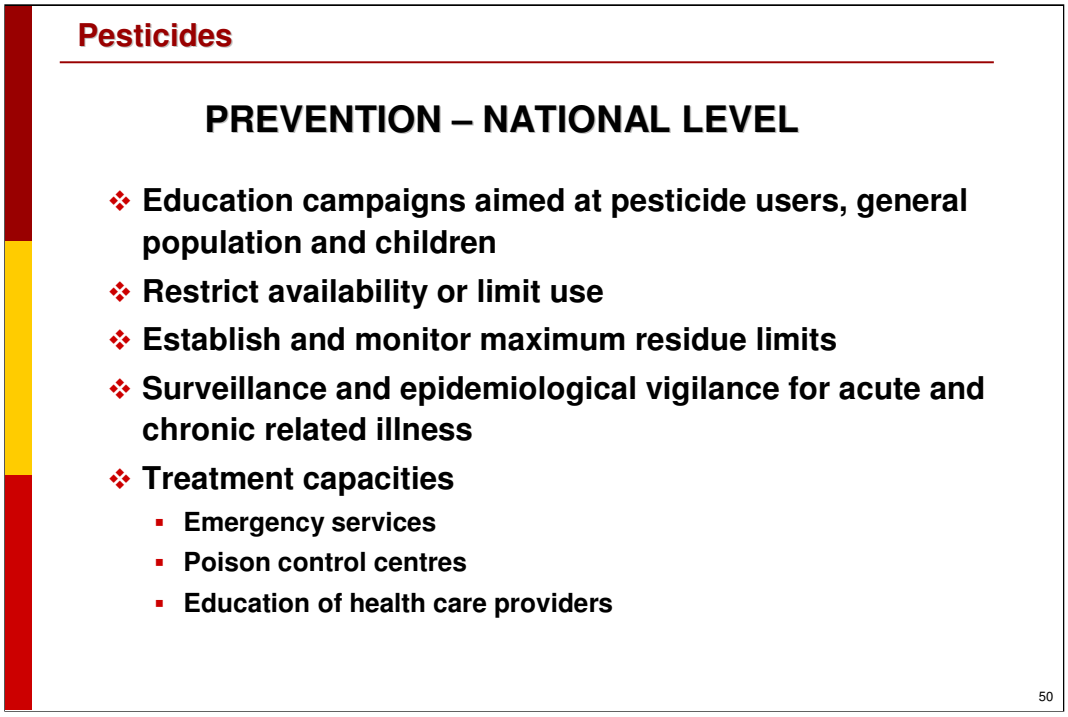
•pesticide-free "zones“

•support for organic farming

FAO: Food and Agriculture Organization

<<READ SLIDE.>>

Picture: WHO, P. Virot. Plants at the Biofarm, Ethiopia, June 2002.



Education is a key component of safe pesticide use and prevention of toxic exposures. Farmers, pesticide applicators and their families need to be informed and educated on how to recognize and prevent pesticide poisonings. Trained or licensed pesticide applicators can maximize preventive measures.

Bans and restrictions on use of pesticides found to be highly toxic or persistent in the environment have been successful; severe poisonings are seen less frequently than in the past. For example, organochlorine poisoning no longer occurs in countries that restrict their uses to a specific agricultural application and have banned domestic use.

A major change in regulatory approaches to pesticides occurred when the US Congress passed the Food Quality Protection Act in 1996. This law requires the US Environmental Protection Agency to set residue levels for foods to protect the most vulnerable populations, specifically infants, children and fetuses (pregnant mothers) from harm due to cumulative exposure taking into account all routes of exposure. This law has led to the restrictions on use and voluntary withdrawal from the market by manufacturers of several previously widely used pesticides (e.g. chlorpyrifos and diazinon).

Pesticide manufacturers and governments should follow the voluntary FAO International Code of Conduct on the Distribution and Use of Pesticides.

Pesticides

PREVENTION – INTERNATIONAL LEVEL

- **Persistent organic pollutants (POPs) Stockholm Convention**
- **Hazardous chemicals and pesticides Rotterdam Convention (PIC)**
- **International organizations: WHO, IFCS, FAO, ILO**

Pronczuk 51

Nine of the 12 persistent organic pollutants (POPs) included in the Stockholm Convention, are pesticides (aldrin, chlordane, DDT, dieldrin, endrin, heptachlor, mirex, toxaphene and hexachlorobenzene). This convention, under the auspices of United Nations Environmental Programme became effective in May 2004, after it was signed by 50 countries.

The Rotterdam Convention on the Prior Informed Consent (PIC) procedure for certain hazardous chemicals and pesticides was adopted in September 1998, and has been signed by 73 countries. The convention establishes a first line of defence against toxic chemicals, giving importing countries the power to receive information and decide which potentially hazardous chemicals they want to receive. It also covers labelling requirements. The convention includes 22 pesticides.

Other international organizations such as the Intergovernmental Forum for Chemical Safety (IFCS), the International Labour Organization (ILO) and others are working towards safer use and monitoring of pesticides at the global level.

IFCS: Intergovernmental Forum for Chemical Safety

FAO: Food and Agriculture Organization

ILO: International Labour Organization

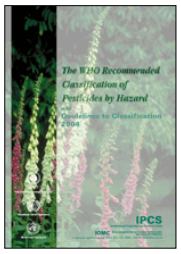
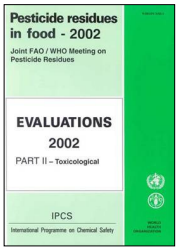
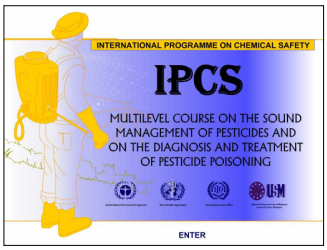
Pesticides

PESTICIDES AND CHILDREN: ACTIVITIES IN WHO

1. **Guidelines for the classification of pesticides by hazard**
2. **Joint FAO/WHO Meeting on Pesticide Residues**
3. **International pesticide limits in water**
4. **Training manual on pesticides**
5. **Poison centres and pesticide exposures**







WHO

52

1. WHO guidelines for the classification of pesticides by hazard. The WHO Recommended Classification of Pesticides by Hazard was approved by the 28th World Health assembly in 1975 and has since gained worldwide acceptance. Guidelines were first issued in 1978, and have since been revised and reissued at 2-yearly intervals. *Ref: IPCS. The WHO Recommended Classification of Pesticides by Hazard and Guidelines to Classification 2000-2002.* Geneva, World Health Organization, 2002.

2. The Joint FAO/WHO Meeting on Pesticide Residues (JMPR) is an international expert scientific group that is administered jointly by the Food and Agriculture Organization of the United Nations (FAO) and the World Health Organization (WHO). JMPR, which consists of the FAO Panel of Experts on Pesticide Residues in Food and the Environment and the WHO Core Assessment Group, has been meeting regularly since 1963. During the meetings, the FAO Panel of Experts is responsible for reviewing information on residues and analytical aspects of the pesticides under consideration, including data on their metabolism, fate in the environment, and use patterns, and for estimating the maximum levels of residues that might occur as a result of the use of the pesticides according to good agricultural practices. The WHO Core Assessment Group is responsible for reviewing toxicological and related data and for estimating, where possible, acceptable daily intakes (ADIs) for humans of the pesticides under consideration.

Ref: www.who.int/ipcs/food/jmpr/en

The Codex Alimentarius Commission was created in 1963 by FAO and WHO to develop food standards, guidelines and related texts such as codes of practice under the Joint FAO/WHO Food Standards Programme. The main purposes of this Programme are protecting the health of the consumers and ensuring fair trade practices in the food trade, and promoting coordination of all work on food standards undertaken by international governmental and nongovernmental organizations. Ref: www.codexalimentarius.net/web/index_en.jsp

3. International pesticide limits in water. WHO produces international norms on water and health in the form of guidelines.

Ref: www.who.int/water_sanitation_health/dwq/guidelines/en/

4. Training manual on pesticides. Available at IPCS (WHO).

5. Poison centres play a key role in providing information, advice and management of case of pesticide exposure in the countries where they are available. For more information, *see*: www.who.int/ipcs/poisons/centre/directory/en/

CRITICAL ROLE OF HEALTH AND ENVIRONMENT PROFESSIONALS

WHO

- Diagnose and treat
- Publish, research
  - Sentinel cases
  - Community-based interventions
- Educate
  - Patients and families
  - Colleagues and students
- Advocate
- Provide role model

Health and environment professionals have a critical role to play in maintaining and stimulating changes that will restore and protect children's environmental health, and protect them from pesticide exposure.

Health care providers can do something. At the one-to-one level with the patient, they can include pesticide poisoning in the differential diagnoses and in preventive advice. They can be dissatisfied with the diagnosis of "idiopathic" in cases of paediatric disease and look harder for evidence pointing to pesticides as a potential cause of disease and disability. They can ask specific questions about the use of pesticides within the home, in the garden or farming areas, or about potential pesticide residues in fruit and vegetables. Which pesticides are being used? When? Where? How? What safety and hygiene measures are being taken? Are the instructions being read and followed?

They can publish sentinel cases and develop and write about community-based interventions in relation to pesticides. They can educate patients, families, colleagues and students didactically to diagnose, treat and prevent pesticide poisonings and exposures. They can discourage chemical pesticide use and encourage integrated pest management. They can also provide information about the local Poisons Centre or other sources of information on pesticides.

As professionals with an understanding of both health and the environment, health care providers are powerful role models who can practice integrated pest management, be advocates for strict pesticide laws and regulations, proper labelling of pesticide products and child-proof containers for all pesticide products.

POINTS FOR DISCUSSION

<<NOTE TO USER: Add points for discussion according to the needs of your audience.>>

Pesticides

CASE STUDY

- **A family with two children ages 8 months and 6 years are referred to the clinic with concerns of pesticide exposure.**
- **They are worried because their apartment was sprayed with pesticides for termites 3 times when the mother was pregnant with her 6 year old son. She remembers feeling dizzy and fatigued during that period but attributed it to the pregnancy.**

<<READ SLIDE>>

The setting is present day New York City, United States. This family is poor and lives in low income housing that was likely sprayed multiple times for termites. The most commonly used pesticide at that time was chlorpyrifos.

Pesticides

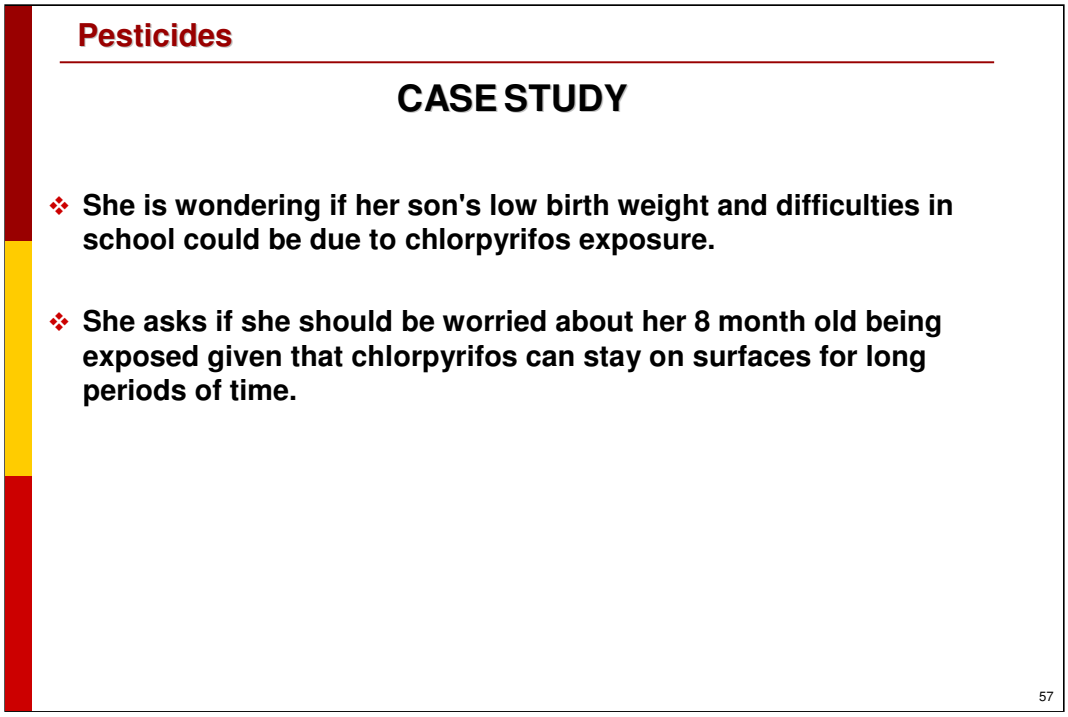
CASE STUDY

- **Her six year old was born at low birth weight for gestational age and has been behind in meeting developmental milestones. He now has behavioural problems and is behind in reading in school.**
- **She recently read in the newspaper that chlorpyrifos is not being used in residential settings in the US because it stays on surfaces for long periods of time and may have harmful health effects.**

56

Read the Slide

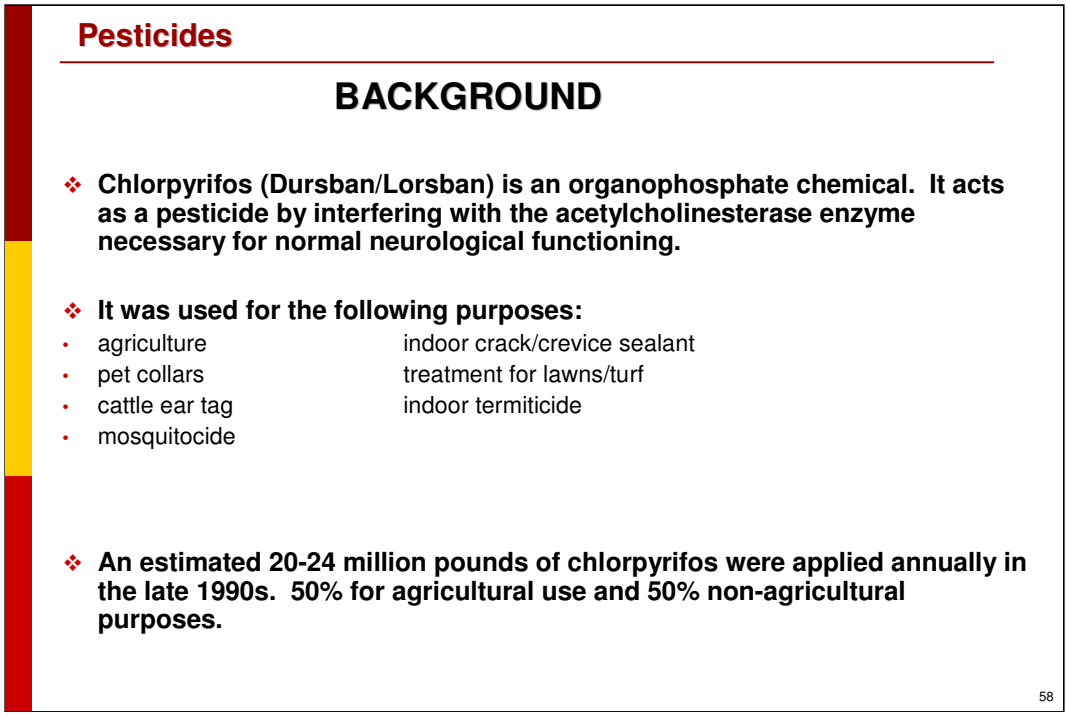
The mother was told by someone at work that there was a newspaper article on a pesticide (chlorpyrifos) that was widely used in their part of New York. It stated that the the US Environmental Protection Agency phased out its use because of adverse health effects. The article pointed out that mothers who were exposed to chlorpyrifos prenatally may have delivered low birth weight babies.



As we know, pediatricians treat the entire family not just individual children. This case brings up a number of interesting points regarding each family member.

Pre-Test

1. What are the problems lists for the 6 year old and 8 month old?
2. What differential diagnoses would you consider for the 6 year old?
3. What further history do you want?
4. How would you further evaluate and manage these patients?
5. What is the likelihood that prenatal chlorpyrifos exposure is related to the 6 year old's health problems?



Chlorpyrifos is in the organophosphate family of chemicals. It is a known human toxin that persists in the environment for decades. Chlorpyrifos is released into the environment and can travel through waterways and sediments to enter the food supply by way of farming or the fish/animal supply. It is ubiquitous in all parts of the world.

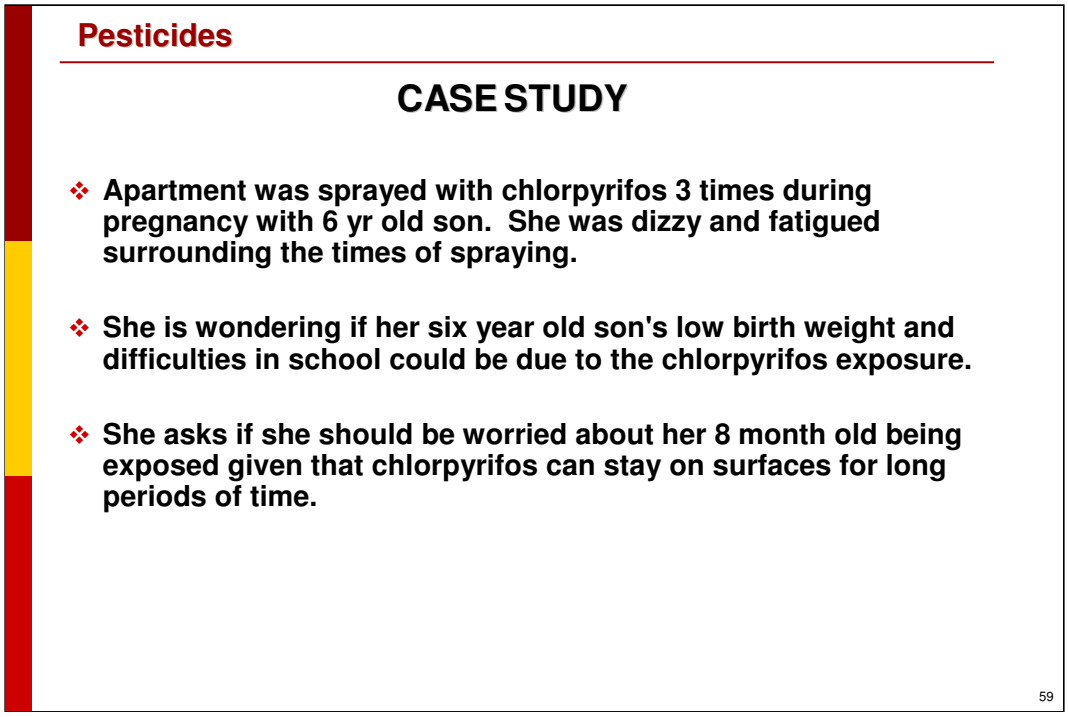
It has been used in farming extensively as a pesticide thereby exposing numerous food crops to its residues.

It has been used as an insecticide for termites and mosquitoes. It has been used as an indoor crack/crevice sealant, for pet collars, and as treatment on lawns, turf or pastures.

US EPA estimates that 20-24 million pounds of chlorpyrifos were applied annually in the late 1990s. Mitigation measures were put into place in the US in 2000 to phase out uses near or in schools, homes, parks, and daycare centers and to restrict uses in agricultural settings.

Ref:

US EPA Website Organophosphate Pesticide Information



Now, let's go back to the original case.

What does this information tell you and what more do you want to know?

1. First, this mother was exposed when she was pregnant. We would like to know the exact chemicals used and have documentation of the exposure. Also, we need to take a thorough environmental history:
- Exposures to other environmental toxicants (there may be other substances in the household contributing to her health effects during pregnancy)
- What are the occupations of the parents? Are there potential environmental exposures at work?
- When is/was the exposure? Is it continuing currently?
- What are the main effects? We would like to know more about the mother's symptoms during pregnancy (although there does not need to be overt clinical symptoms for low level toxicity).

2. In terms of the six year old son – we would like to know his birth weight, length, and head circumference
- How has his growth has been?
- What is his developmental history?
- What are his activities and what he might be exposed to in the environment?

3. In terms of the 8 month old, we would like to know if he is crawling currently (exposure to floor, carpets, furniture).
- Is he still breastfeeding?
- How has his development been?

ANSWERS

Overall, there are not clear cut answers in low dose exposure toxicology as compared to acute exposures. All answers must weigh the scientific evidence of the toxicant against the clinical history and physical exam findings of the patients.

1. Chlorpyrifos exposure in high doses is associated with dizziness and fatigue. The differental diagnosis for her symptoms is long and, it is difficult say whether the mother's symptoms were due to this exposure given that most residential chlorpyrifos sprayings were not associated with overt toxicity.
2. Her son's low birth weight and difficulties in school may be due to a number of factors. Chlorpyrifos has been associated with low birth weight and decreased birth length in inner city newborns whose mothers were exposed during pregnancy. Long term neurodevelopmental outcomes have not been studied to date.
3. The 8 month old is crawling and being exposed to many surfaces in the home. The data has shown that higher levels of chlorpyrifos are inversely correlated with time from application to testing. Most of this data shows that residues persist for 1-2 wks after spraying but with multiple exposures, residues may persist longer.

CASE STUDY

What recommendations would you give to this family?

- **Primary prevention!**
- **Encourage home dust/furniture testing if they think exposure is ongoing**
- **Encourage blood testing for acetylcholinesterase if they are worried about ongoing exposures**
- **Encourage alternatives to pesticides for the future**

Pesticides

ACKNOWLEDGEMENTS

WHO is grateful to German donors and to the US EPA Office of Children's Health Protection for the financial support that made this project possible and for some of the data, graphics and text used in preparing these materials.

Tool Talk
Tools that every gardener should know about.

There is a huge variety in tools sold for gardening.

In the end, it comes down to personal preference…

Today's presentation:

- Basic tools and uses (with demos)
- The short list of tools every gardener should own.
- Unusual Tools
- Uses for Old Tools
- Sources for Buying Tools

Basic Tools: Hoes – pull (more common)

General purpose Hoe

Stirrup or Cultivator Hoe

Vee Hoe

Purpose:

- Break up soil
- Chop weeds
- Move soil
- Make rows

Field Hoe

Hoe Dag

Basic Tools: Hoes – push or "Dutch" style

"Dutch scuffle" – not a dance

Royal Dutch Hoe (made by SneeBoer)

Main purpose:

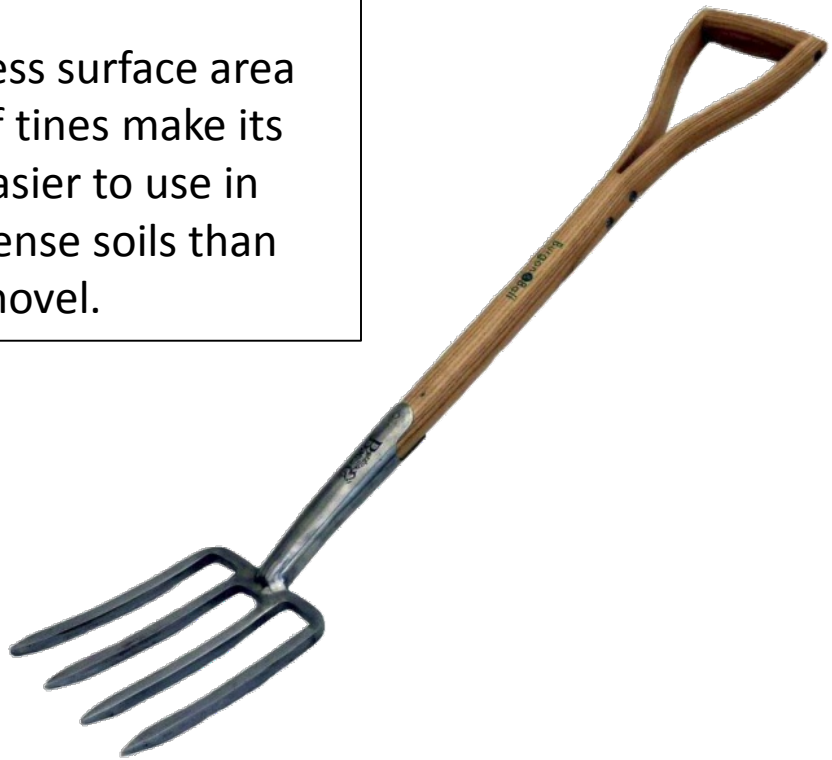
- Eliminate weeds

Basic Tools: Garden Fork

Flat tines

Purpose: Turn soil

Less surface area of tines make its easier to use in dense soils than shovel.



Basic Tools: Shovels

Shovel

Purpose:
Digging

Spade

Purpose:
Digging; turning soil; breaking up clods

Trenching Spade

Purpose:
Digging deep; turning soil

Scoop Shovel

Purpose:
Moving soil, compost, etc…
NOT FOR DIGGING

Basic Tools: Garden Rakes

Bow Rake

Purpose:
Smooth out beds

Totally different beasts!

Leaf Rake

Purpose:
Collecting Leaves

NOT FOR MOVING SOIL!

Not so Basic: Broad Fork

TreadLiteTools – $105 + 40 shipping from Appleton, WI

Basic Tools: Hand Tools

Weeder

Purpose:
Can penetrate soil to loosen roots during weeding

Hand Trowel

Purpose:
Local Digging; Planting; Weeding

Hand Rake

Purpose:
reaking and loosening soil;

Basic Tools: Hand Pruners and Saws

Anvil Style – Best for cutting dead shoots and branches

Bypass Style – Best for cutting live plant material. Can jam with dead wood.

Folding Hand Saw

Purpose:
Cutting large woody branches

Short list –
<u>Tools every gardener should own</u>

- One Preferred Digging Tool: Spade, Garden Fork or Shovel
- Multi-purpose Hoe
- Bow Rake
- Hand Trowel
- Hand Pruner

There are lots of other useful tools too….

Unusual Tools

These cross the line with culinary tools

Unusual Tools

Scary looking

Turning old tools into art

Turning old tools into furniture

Getting started in the garden

Whether you are starting a new garden from a fresh plot or are developing an existing garden you have acquired, it will always involve a certain amount of care. To help you be as efficient as possible in the garden you will require the right gardening tool for the right job. Many of these core tools will be in constant use so choosing good quality, reliable equipment that is lightweight and comfortable in use is important.

Gardening is a very rewarding leisure activity – it offers you exercise, fresh air, a feeling of achievement and in return can provide you with either a lovely garden, which is an extension to the living area of your home, or garden grown vegetables to eat, or even both. So whether you want to create a relaxing outdoor space to enjoy or establish a vegetable and fruit growing area, you are going to need the right tools to help you do it.

On these pages we highlight some of the key tools you will need for a new garden. There may be others you find you need but these will give you a good mix of tools along with other equipment to get you started. Or if you have a mature garden which now needs a greater focus on maintenance you may find our suggested list of maintenance equipment useful.

An introduction to multi-change®

Gardening without the backache!

Our multi-change® range is specifically designed to be lightweight and comfortable to use.

The 'every tool head fits every handle' multi-change® range comprises of a selection of 15 handles of different lengths (to suit your height or the task at hand) and over 60 tool heads to cater for any type of gardening task.

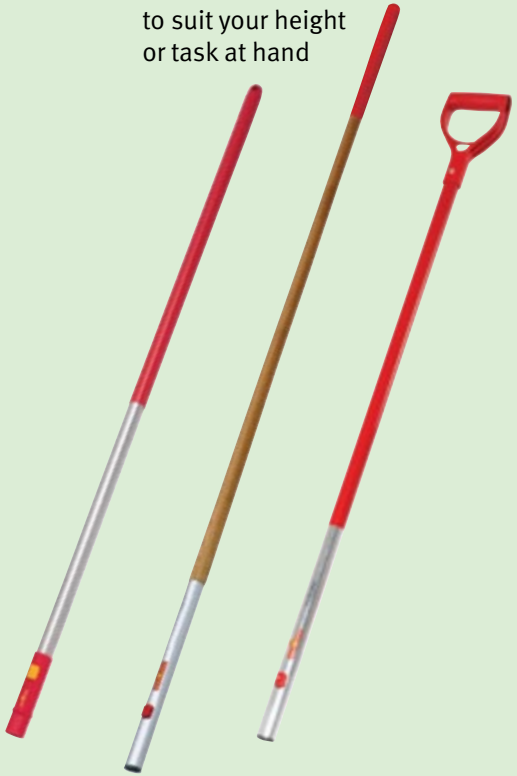
When you find a handle that you love, you can choose from our comprehensive selection of tool heads and just 'click' them together to get any gardening job done with a straight back. When you have your handle, you can keep adding to your collection of tool heads as it only takes a quick press of a button to release one tool head and swap it for another.

Every tool head in this collection is designed to fit whichever handle you purchase so you can convert from cultivating to weeding to raking by switching tool heads and using the same handle, saving you storage space, money and most importantly a lot of backache!

WOLF-Garten provides superior-quality materials, excellent workmanship, innovative function and excellent design. All features which are bundled in the WOLF-Garten quality guarantee of 10 years on all multi-change® tools.

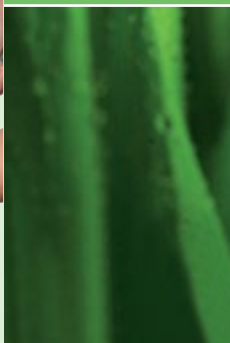
multi-change® in 3 easy steps

STEP 1 Select a handle to suit your height or task at hand



STEP 2 Choose the appropriate tool head for the task in hand

STEP 3 Simply click the tool head onto the handle



multi-change® Handles

A handle is the starting point for any multi-change® collection, whether it's for general use or for a more specific application.

All of our lightweight metal handles are made using recycled aluminium, while our wooden handles are FSC® certified.

Each handle has a fixed seat guaranteed to withstand vibration and absorb shock when in use.

ZM02	Small Handle
Length	15cm
Trade Pack	10
RRP	£4.99

- Suitable for use with hand saws and rockery tools
- Push button tool head release on handle end

4 009269 394307

ZM04	Small Handle
Length	35cm
Trade Pack	5
RRP	£6.99

- Suitable for use with hand trowel and fork
- Made from lightweight, strong, high quality aluminium

4 009269 394482

ZMAD	Aluminium D-Grip Handle
Length	85cm
Trade Pack	5
RRP	£9.99

- Made from lightweight, strong, high quality aluminium
- Comfortable plastic sleeve

4 009269 166003

ZMAD120	Aluminium D-Grip Handle
Length	120cm
Trade Pack	5
RRP	£19.99

- Made from lightweight, strong, high quality aluminium
- Comfortable plastic sleeve
- Fits all multi-change® tool heads

4 009269 394277 >

ZMV150	Telescopic Handle
Length	90-150cm
Trade Pack	6
RRP	£24.99

- Adjustable in length
- Fits all multi-change® tool heads
- Made from lightweight strong, high quality aluminium

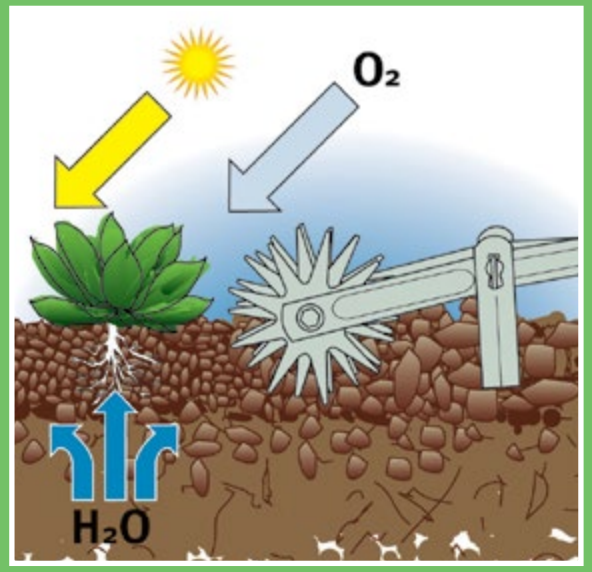
4 009269 397001 >

multi-change®
Cultivation Tools

The multi-change® Cultivation Tool range incorporates all the tools needed to keep borders in blooming good health, as well as the tools required for an allotment area. Each tool has a solid, robust design with tines, prongs and blades that will resist bending, wear and corrosion.



BAM	Grubber
Width	9cm
Trade Pack	5
RRP	£15.99

- For breaking up soil between plants in beds and borders
- Sharp pointed prongs for hard and stony ground

4 009269 110006

BEM	Cultivator
Width	11cm
Trade Pack	5
RRP	£18.99

- Lance shaped prongs break up medium soils for good nutrient distribution
- Durable zinc chrome plate and lacquer finish

4 009269 111003 >

IEM	Cultiweeder
Width	10cm
Trade Pack	4
RRP	£19.99

- Lance shaped prongs break up and loosen soil
- Sharp weeding blade on rear cuts through weeds fast

4 009269 138000

BIM	Aerator
Width	3.5cm
Trade Pack	5
RRP	£15.99

- Loosens soil with ease in confined spaces, for optimum nutrient distribution
- Extra hardened with lacquer finish

4 009269 112000 >

ILM3	Double Hoe
Width	8cm
Trade Pack	5
RRP	£16.99

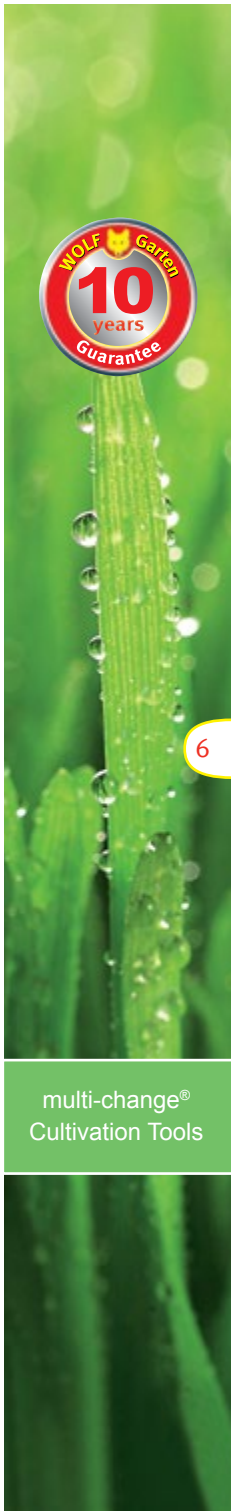
- Broad, sharp angled blade for weeding or drawing out seed drills
- Sharp prongs on rear break up heavy soil

4 009269 139403

DAS	Soil Miller
Width	15cm
Trade Pack	3
RRP	£44.99

- Crumbles soil into a fine tilth for sowing seeds or planting
- Mixes peat, manure and fertiliser into the soil
- Rear blade keeps tool at a constant depth

4 009269 117203



multi-change®
Cultivation Tools

multi-change®
Cultivation Tools

JAM	Ridger
Trade Pack	3
RRP	£29.99

- For producing up to 20cm wide furrows for planting potatoes etc
- For ridging up and earthing up around plants

4 009269 138505

EAM	Seed Sower
Trade Pack	5
RRP	£15.99

- Saves time and effort by sowing seeds uniformly in rows without bending
- 6 adjustable seed size settings - up to pea size

4 009269 181402 >

DSM19	Close Toothed Rake
Width	19cm
Trade Pack	5
RRP	£13.99

- Rake with curved teeth which are easily pulled through soil and gravel
- Durable zinc chrome plate and lacquer finish

4 009269 122900 >

DRM30	Soil Rake
Width	30cm
Trade Pack	5

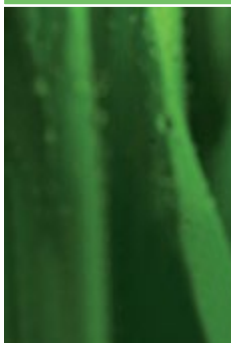
Sweeping Tools



Secateurs

There are so many secateurs, how do you know which one to use? Well, like loppers, that all depends on the cutting job in hand. Is it trimming new stems or tougher woodier growth?

Bypass Secateurs work on a scissor like cutting action with one blade 'bypassing' the other. They are ideal for cutting growth which is younger (up to 2 years old) as they provide a very clean cut, essential for maintaining a healthy plant or shrub. Little pressure is required in pruning of this nature so the secateurs themselves are light in weight. Bypass Secateurs can still be used on older cuttings but a little more effort will be required by the user.

For older thicker stems, it is best to use an Anvil Secateur to reduce the strain on the wrist and hand. With Anvil Secateurs the blade closes against a softer metal on the lower jaw, this does not produce such a clean cut as a Bypass Secateur, which is why it is not suited to young stems but more to older wood where the cleanliness of the cut is not so important. Always consider the density of the wood you are cutting and ensure you have the right tool for the job; you may want to upgrade the cutting tool to avoid unnecessary strain on the hand.

RREN	Bypass Secateurs
Cutting Diameter	19mm
Trade Pack	5
RRP	£16.99

- For delicate and precise pruning
- Suitable for both left and right handed use
- Coated blades for non-stick pruning and easy cleaning

- Easy to replace anvil block

4 009269 730402 >

Loppers

A simple rule for choosing the right lopper is bypass for younger branches and anvil for hardier or dead wood. It is especially important to ensure you use the right tool for the job when cutting greener branches as the bypass lopper allows for a more accurate cut without crushing the branch.

Be sure that the lopper will be able to make one clean cut, otherwise you cause multiple wounds to the branch that can attract insects or disease more quickly. The longer the handles, the more leverage you will have when cutting, making it easier to achieve a clean cut. Telescopic loppers are available in the WOLF-Garten range to reach taller bushes.

RR530	POWER Cut Bypass Lopper
Cutting Diameter	30mm

Simple, efficient and leading-edge: 72V lithium-ion battery power

Better for you, your garden and the environment
The new, ultra-modern 72v rechargeable battery technology – exclusively developed by WOLF-Garten – is extremely powerful.

It is quiet, kind to the environment and requires almost no maintenance and upkeep. With these cordless, lightweight rechargeable battery power tools, garden work will be sheer pleasure.

Weather it is using the lawnmower, grass trimmer, hedge trimmer or leaf blower – the 72v rechargeable batteries deliver immediate power and offer the longest time of all comparable battery-powered garden tools. An integrated cooling and ventilation system prevents overheating and guarantees longer service life and safe charging.

The charging time with the 72v charging station is just 1 hour and 80% recharge in just 45 minutes – making it one of the fastest chargers on the market.

Very durable / No self discharge / Economical, quiet and environmentally friendly / Extremely light, handy and agile.

One rechargeable battery for all 72v garden tools

NEW 72V Battery Range

Versatile, lightweight and cable free powered garden tools

The WOLF-Garten 72 Volt Li-ion power battery garden tool range is an interchangeable battery system that delivers powerful garden tools without engine fumes, tangled cables or short run times. The perfect lightweight powered tool collection of a grass trimmer, lawnmower, hedge trimmer and leaf blower.

30T GRASS TRIMMER	72V Li-ion Power

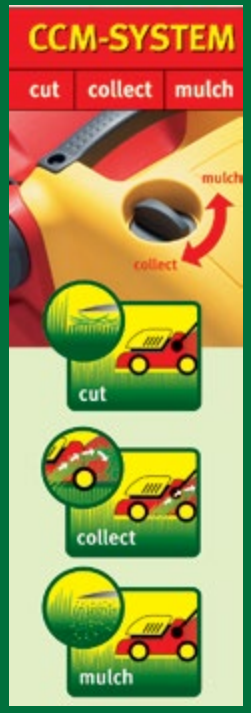
LAWNMOWERS

WOLF-Garten provides a wide array of powerful, light-weight and extremely manoeuvrable lawnmowers to help maintain a beautiful lawn. This includes hand push, electric and expert ranges, along with a new cordless 72V Li-ion power battery range offering a cable free alternative. With options to choose between collecting grass clippings in a grass bag or mulching clippings back into the lawn, WOLF-Garten lawn-mowers feature technological innovations to help keep lawn mowing easy and enjoyable.

CUT, COLLECT, MULCH

Flexible mowing systems offer a choice between cutting, collecting or mulching. The CCM-System integrates all these functions with timeless design and constant technological innovation.



The advantages of mulching are:

- It saves time and effort as the collection bag doesn't need emptying
- No disposal of clippings
- The clippings provide the lawn with moisture and valuable nutrients

72V Battery Range

The cable free alternative

The WOLF-Garten 72 Volt Li-ion power battery lawnmower range is characterised by beautiful design, modern 72V Li-ion power battery technology and sophisticated cutting systems. With lightweight chassis, super quiet operating and no cables to get tangled, they provide the ultimate freedom around your garden.

The Triplex System® - mowing faster, better, cleaner!

On Expert electric mowers our patented Triplex System® guarantees the absolute filling of the collecting bag, with either dry, wet and/or high grass. During mowing, the clippings are sucked in by a heavy flow of air, this circulation is created by the rotation movement of the precision blades.

Shredders, Tillers and Scarifiers

The WOLF-Garten Universal Shredder converts garden waste into valuable compost or mulch. The cut and crush action of the cutting system can convert even woody waste up to 40mm diameter into quality compost, quickly and quietly. Processed material can be used as mulch on borders and beds.

The WOLF-Garten Scarifiers remove organic matter from around the grass roots and tidy up any straggly lateral growth. When this layer of thatch and moss is removed, vital nutrients, oxygen and water can penetrate the soil to be absorbed by the grass roots, encouraging lawn re-growth.

VS302E	1200W Electric Scarifier
Working Width	30cm
Trade Pack	1
RRP	£149.99

Bound by tradition – the story of WOLF-Garten

It all began with minor inventions that put the WOLF company on the map. One of the first achievements was the draw hoe, a tool designed to make agricultural work easier. Gregor Wolf developed it in 1927 in the ironware factory that his father August Wolf had founded together with his sons Gregor and Otto in 1922. The idea first came to him on his way home from work, while observing local farmers working their fields.

This initial innovation was followed by many others. In 1953 the WOLF Geräte GmbH was the first company in Europe to offer lawnmowers with rotating blades. In 1958 WOLF introduced the first electrical lawnmower to the European market prior to developing the world's most silent petrol lawnmower in 1975.

Over the years, the company has developed a clear and distinctive profile in the “green area”. The WOLF Geräte GmbH of the early era became WOLF-Garten, an established company known for their key skills regarding product quality, product diversity and gardening know-how with an expertise in environmental awareness. The focused research and development work in its own research institutes was just as important for their growth as the development of new market segments.

Later global innovations helped give the brand the distinctive wolf face on a red background. WOLF-Garten is highly successful with its innovative multi-change® system that has guaranteed top quality for more than 30 years and confidently provides a 10-year warranty for all associated products. The development of innovative seed and fertiliser products, as well as the extension of its lawnmower range have demonstrated the strength and diversity of the company. WOLF-Garten was one of the first companies to offer a wide range of versatile lawn tractors to the European market. Handheld all-season tools and special devices for winter use round off the WOLF-Garten range.

WOLF-Garten promotes environmentally compatible technologies in times of climate change. The BluePower program, which extends through most product groups, clearly show the commitment of WOLF-Garten.

Numerous quality awards and excellent results in comparative testings document why the trust of novice as well as professional gardeners throughout Europe is justified by the quality and innovative strength of WOLF-Garten. Making garden work easier, more enjoyable and more environmentally compatible will guide our corporate future like a green beacon. This goal is fully supported by our employees. It is them who ensure the familiar reliability, the high quality standard of the company and the inexhaustible innovative drive of WOLF-Garten.

To assure you of the quality of our range, all garden tools come with a 10 year guarantee for manufacturer's fault (not wear and tear). The electric range also comes with a guarantee of between 3 and 5 years depending on product.

Gardening Equipment

Alex X. Niemiera, Extension Horticulturist, Virginia Tech

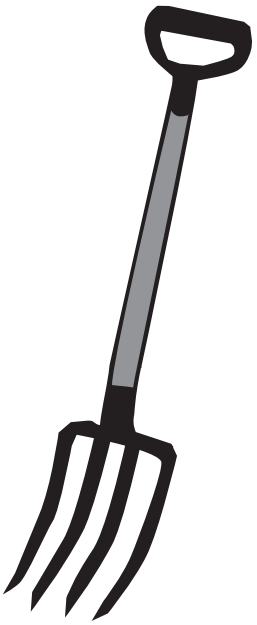
Gardening Equipment

Garden catalogs and stores are full of gardening tools, many highly specialized; some are very useful, others are nice but not necessary, and some are gimmicks. The gardening equipment you need depends on the size of your garden, your age and strength, and whether you want to get the job done in a hurry or prefer to take your time. The basic equipment needed by most gardeners (for vegetables or the landscape) includes a shovel or spade, a hoe, a rake, a trowel, and pruning tools. A wide selection of styles is available in each of these tools, and the choice is really one of personal preference and price range. You can get the best value for the price range you choose by knowing each tool's uses and particular qualities when comparison shopping. You'll get the best deal by buying tools at the end of the gardening season when prices are reduced.

Tools for Cultivating

Hand Tools

A garden **shovel** has a concave pointed blade that is mounted to the handle at an angle and is designed to dig holes and move soil. A **spade** has a flat blade and is designed for cutting rather than lifting or moving soil. Spades are excellent for shaping straight-sided trenches, transplanting trees and shrubs, cutting roots, and for edging beds. There are many variations on spade blade shape and size. For general-purpose digging, lifting, and moving, a long-handled shovel is ideal. Shovel and spade handle styles are either long or short with a straight shaft or a D-shaped handgrip. The choice of handle style depends on personal preference; long handles offer greater leverage and are less tiring to use in many cases.



Garden and spading forks have four tines and are used for turning over garden soil**.** A garden fork has thick rectangular or square tines and is used for turning over unbroken soil, heavy cultivation, or soil with large clods. A spading fork has flat tines (sometimes with diamond of triangular backs) and is used for turning already loose soil. Forks are also useful to turn over compost, spread mulches, and to dig root crops.

A **hoe,** depending on the design, is used for preparing seedbeds, making furrows, removing weeds, and breaking up encrusted soil. For weeding, hoes remove shallow-rooted annual weeds and sever the tops off of biennial or perennial weeds. In the later case, weeds will most likely regrow from the root system. Several different hoe styles are available, each with several variations. The most common type of hoe is the draw hoe, also called garden or common hoe that has a rectangular or square flat blade. Variations of this type blade include the nursery hoe

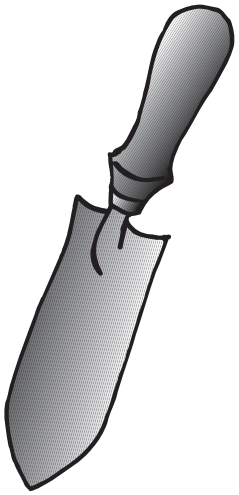
VT/0906/W/426315

(a heavier blade), the cavex hoe (a curved rather than straight cutting edge) and the swoe (blade attached to the shaft as a golf club). The pointed hoe with a heart-shaped blade is lightweight and useful for opening seed furrows and cultivating between plants. Variations of this type include the Warren hoe and the Korean hoe. The hula (scuffle, shuffle, push-pull, or action hoe) is shaped like a stirrup (D-shaped) and is very lightweight and maneuverable. Variations of this type include the Dutch scuffle hole and types with movable blades (action hoes). Pushing and pulling it just under the soil surface eliminates newly emerging weeds and breaks up any crust on the soil surface. This type of hoe is most easily used on soil which is not compacted, since the blade is relatively thin and lacks the clod-breaking capabilities of a heavier hoe; it is also less effective in cases where weeds have gotten a good start. Some types of scuffle hoes are somewhat sturdier and are used with a pushing motion rather than pushing and pulling.

There are essentially two types of **rakes**, a garden rake and a lawn rake. A garden rake has stiff metal tines and is used to clear rocks and debris from the garden, spreading mulches, and smoothing seedbeds. A lawn rake has numerous thin flexible tines usually made of metal, plastic, or bamboo. A "leaf rake" is a version of the lawn rake that has shorter tines. Lawn and leaf rakes are used to rake leaves and gather loose plant debris, and come in several sizes. There are other rake types specifically designed for grading and removing thatch from lawns. The size and weight of the rake that is best suited to you depends on your size and strength, and the intended uses. The length of the rake handle is important; the tip of the handle should come up to your ear when standing upright. A handle that is too short will make your work harder, causing excess bending and back strain.

A **trowel** is especially useful for those many digging tasks that require a finer degree of control or are performed in a relatively small area. The trowel is perfect for transplanting seedlings and bulbs, or digging shallow-rooted weeds. Small hand cultivators, often sold in sets with trowels, are good for weeding in small areas and between closely spaced plants. Another useful, small digging tool is appropriately named a **digger** (a.k.a. weeder, cultivator, asparagus knife). This tool is available from most hardware or discount stores and is useful for digging up weeds with long taproots, such as dandelions or Queen Anne's lace, or for prying out Johnson grass rhizomes. A digger consists of a long (10 to 14 inches), solid-metal rod with a two-pronged blade at one end and a handle at the other.



Some other tools that may have a place in the garden tool shed include the pickax, mattock, and wheel cultivator. Pickaxes are used to break up extremely hard-packed or stony soil. Mattocks are for the same purpose, but are equipped with a cutting blade for areas where larger roots need to be removed. A mattock may also be used to chop up debris for composting. A wheel cultivator has a number of attachments for soil preparation and weed control, and may prove a good investment for those with larger gardens.

Hand tools may have a wood, plastic/fiberglass (or other composite material), or metal shaft. Of course, steel is the heaviest but the strongest. Wood and fiberglass are the lightest but least strong. Your choice of shaft material will depend on the amount and type of work you do, your preference for shaft weight, and cost (steel is the most expensive). There have been a number of significant improvements in garden-tool handle designs to make tool use more ergonomically effective and more comfortable to operate.

Power Tools

The power **rotary tiller** is probably the power tool most commonly purchased by gardeners. Whether or not a gardener needs a rotary tiller depends on the size of the garden, the gardener's capabilities, and the intended uses of the tiller. Renting a tiller or hiring someone to till the garden meets the needs of most gardeners. If a tiller is to be purchased, tiller selection may be based on the nature of the work to be done, the quality of the machine and ease of repair, as well as personal preference. The tiller's engine powers rotating blades, or tines, which make garden soil loose and ready for planting. It can also chop up plant debris and mix it into the soil. Incorporating organic matter and manures into the garden is easily accomplished with a tiller, an otherwise laborious

chore by hand. The ability of the tiller to do these jobs effectively is a function of its weight, strength, design, and type of tines, as well as the type of soil. A heavy, powerful tiller is most effective on stony, clay soils, while in a small garden or one with light soil, a smaller tiller is more appropriate. Very lightweight tillers, known as soil blenders, are designed mainly for raised-bed or loose-soil gardening.

Rotary tillers are available with front-mounted or rear-mounted tines. Rear-tined tillers generally have self-propelled wheels; front-mounted models do not. Rear-tined models are easier to keep driving straight and to control tine depth, and can produce a footprint-free seedbed if you operate the tiller with one hand and keep to the side. Rear-tined tillers often have a number of attachments available for a variety of uses, such as hilling potatoes, making raised beds, even plowing snow! The price of a rear-tined rototiller is considerably higher, in most cases, than that of the front-tined type; consideration should be given to the payback time necessary for such a large investment. Most tillers operate with the tines moving in the same direction as the wheels (forward tine rotation). Some models have a reverse tine rotation in which the tines move opposite the rotation of the wheels. The proposed advantage of reverse tine tillers is that they are more effective in breaking up hard ground. However, if the tines of a reverse tined tiller catch hold of a root or rock, the tiller is apt to jump back. Such a jump back action may pose a safety hazard to the operator.

If gardening is simply a hobby, or if the garden is small, a front-tined tiller may be suitable. Front-tined tillers are usually light in weight, but may require considerable strength to guide them through the soil. Operating this type of tiller is comparable to handling a large floor polisher, such as those used in schools and hospitals; mainly, leverage is required for control. New gardeners are sometimes deterred from using these tillers because of the initial experience of having a tiller run away from them. The front-tined tiller may not make as straight a pass as the heavier, rear-tined type, but it is much easier to turn. Due to this increased maneuverability, the front-tined tiller is easy to use in small gardens and in corner areas.

The purchase of a tiller is a major investment. Features to look for include heavy cast-iron, steel plate and tubing, heavy bearings, strong welds used in construction, and easily operable controls. Ask to look at the operator's manual and try to determine how simply a tune-up can be performed; you may save yourself a great deal of trouble and money if you can do the work yourself, particularly if you have no truck on which to load the tiller. Also consider the locations of service centers and parts dealers. Careful attention to your needs, abilities, and price range is important. Talk to people who have the types of tillers in which you are interested. If possible, borrow or rent various types of machines and send for information before buying.

If you do not know much about such equipment, it might be helpful to have a mechanically minded friend look over the machines you are considering. Above all, test each tiller for ease of starting and operation. For used tillers, an engine that smokes or runs roughly may require a lot of work. Tines should operate smoothly and freely. Check the welds in the handles to see that they are strong; rewelding may mean that the handles have broken at some time, a common problem in older tillers. Look at the dipstick, if there is one; low oil or very sludgy oil may mean that the tiller has been maintained poorly. Oil and other fluids may also be checked by opening the drain plugs. Look for excessive dirt around the engine or in the air filter. This may also mean bad maintenance habits. Ask the owner for an operator's manual, and ask where the machine has been serviced in the past. A good tiller is a long-term investment, so plan carefully before you buy.

Other Power Tools

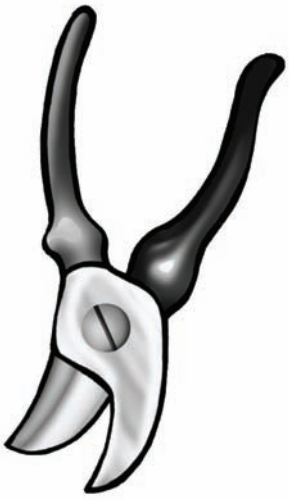
There are few other power tools needed in the vegetable garden. Cordless tools come with various cultivating attachments. Most are rechargeable and can make garden chores more pleasurable; these tools are especially useful to those with physical disabilities or limited strength. However, these tools only work effectively in a bed high in organic material and free of coarse debris.

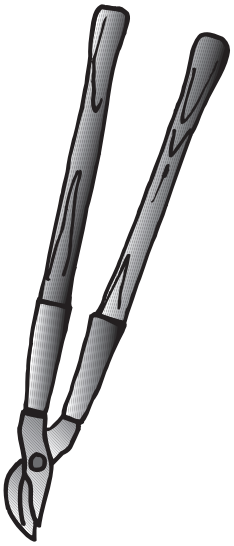
A garden shredder may be useful for a large garden with a lot of plant wastes. There are hand-operated shredders that are slow but useful if wastes become avail-

able in small quantities and are not too coarse. Gasoline shredders are quite expensive and may be disappointing to the gardener who wants to chip branches and other large materials. They are best used for shredding leaves, small branches, and other plant wastes (though sunflower stalks would probably be too much for one). They are also noisy. A chipper, on the other hand, will chip large branches and other coarse material, but the cost of $1000 or more makes the chipper uneconomical for the home gardener. **Wear the necessary head, ear, and eye protection, and heed all manufacturer's operation and safety recommendations when using power tools**.

Pruning Tools

Pruning shears are good for branches up to one-half to three-quarters of an inch in diameter. Attempting to cut larger branches risks making a poor cut and/or ruining the shears. There are two types of pruners 1) two blade or cut styles of hand shears: scissor action (also called bypass blades), and 2) anvil cut. In the anvil style, a sharpened blade cuts against a broad, flat plate. In the scissor style, a thin, sharp blade slides closely past a thicker (but also sharp) blade. The scissor style usually costs more, but makes cleaner, closer cuts. When buying pruners, test the pruners in your hand to make sure you can hold them comfortably. If they are too large or small, too heavy or too hard to squeeze, try another style or brand; there is a wide variety of pruning tools available. If you have trouble using pruning tools, there may be special equipment available to suit you. For example, ratchet pruners are useful if your grip is not strong because they can be closed easily with very little pressure.

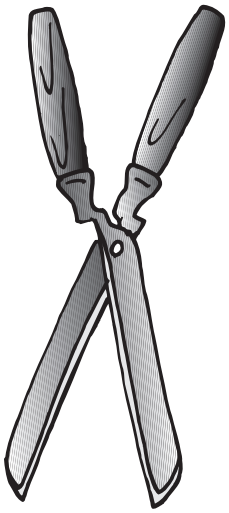




Lopping shears have long handles and are operated with both hands. Loppers are designed to cut branches that are more than one-half to three-quarters inch in diameter. Loppers are best used for shrub pruning and not for trees due to 1) accuracy of cut, 2) maneuverability, and 3) difficulty in making a clean cut for a large branch. Tree branches that are larger than three-quarters of an inch (and up to 4 inches) in diameter are cut more easily, accurately, and with less damage using a hand saw than with loppers.

Pole pruners have a cutter with a hooked blade above and a cutting blade beneath. The cutter is on a pole and is operated by a cord or chain pulled downward. For the same reasons as described for the loppers, the hook and blade mechanism has limited use on tree branches. Fully extended, pole pruners reach branches 12 feet or more above the ground. The poles can either be in sections that fit together or telescoping. Wooden poles are heavy. Aluminum poles are light but can conduct electricity if they touch an overhead wire. Fiberglass or some type of plastic compound is probably the best answer. Poles can be fitted with saws, but saw cuts can be difficult to make due to the awkwardness of the available cutting angle. Using pole pruners can be dangerous, as material cut overhead can fall on the operator (unless it hangs up in other branches); exercise caution and wear head and eye protection. Obtaining an accurate pruning cut with a pole saw is relatively difficult for those who have little pruning experience. Consider employing a professional to make those cuts that you cannot easily reach with a ladder and shears or hand saw.

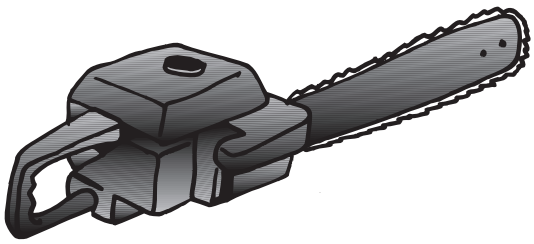
Hedge shears have long, flat blades and relatively short handles, one for each hand. Heavy-duty shears, with one blade serrated, are good for difficult jobs. Power hedge shears are also available. The most common for home use are electric models. Although these are efficient for shearing, they often result in ragged cuts that are entry points for insects and diseases. Keep blades sharp. If there is a choice in plants, consider using a small plant that will not need shearing.



There are many makes and models of **pruning saws**. Fineness of cutting edge is measured in points (teeth per inch). An 8-point saw is for delicate, close work on small shrubs and trees. Average saws are about 6 points, while 4 1/2-point saws are for fairly heavy limbs. A fixed-blade saw with a protective scabbard is safer and easier to use. Folding saws often require either

a screwdriver (for a slotted-head holding screw) or will have a protruding wing nut, which can scar the trunk when a limb is cut. If the saw suddenly folds while in use, the operator's fingers can be damaged. Blades can be either straight or curved. Many prefer a curved blade that cuts on the draw stroke. A double-edged saw has fine teeth on one side, coarse on the other; these can do significant damage to surrounding branches and may be difficult to use in densely branched plants. Bow saws are good only where no obstruction exists for a foot or more above the area to be cut.

Chain saws come in a variety of sizes, both gas and electric. Chain saws are used to remove large limbs or entire trees. Chain saws should be used only with appropriate safety gear by people who fully understand their operation and handling for pruning. Improper or careless handling can do significant damage to trees in a very short time. Therefore, the use of chain saws is generally not recommended for homeowners.



Carts/Wheelbarrows

A wheelbarrow or cart is very handy to have in and around the garden area. Select one that is easy to handle when full, with good maneuverability. Durable construction is well worth paying for to ensure a long, useful life. Be sure to choose the size appropriate for your physical abilities and garden needs. A wheelbarrow generally requires more strength and control than do most garden carts, however, there are two-wheel wheelbarrows that are much easier to control than the one-wheel type.

Many of the small carts generally available are made of relatively flimsy metal and, though inexpensive, are not particularly long lasting or suitable for heavy items such as rocks. Again, consider your needs. If you plan to haul only light straw, leaves, sawdust, and such materials, then one of the small carts may be suitable. For heavier jobs, you may need a wheelbarrow; or investigate some of the newer garden carts, especially those with bicycle-size tires, which make easy work of hauling. They are made of heavy plywood and metal, but are well balanced and easy to maneuver. These carts do, however, involve a sizeable investment (up to several hundred dollars) and a large storage space. Therefore, only serious gardeners or those with other uses for such a cart find them economical. One alternative is to build your own from one of several plans available from gardening magazines or private companies.

Pest Control Equipment

Pest control equipment is needed in most gardens. Even organic gardeners often need sprayers for dormant oils or dusters for botanical insecticides. There is a wide range of available equipment ranging from simple and cheap to sophisticated and expensive. Here again, one's own needs and budget are the determining factors.

Using the same spray equipment for weed and insect control is neither safe nor desirable. No matter how well a tank is rinsed after using some herbicides, a residue may be left in the tank, gaskets, hoses, and other parts. If the same equipment is then used to spray a plant with insecticide or fungicide, the herbicide residue may kill or injure the plant. The wisest policy is to maintain two sprayers, one for herbicides and another for insecticides and fungicides. Label each sprayer accordingly. Sprayers should be rinsed after each use. Don't forget to flush hoses and nozzles. Sprayers must be kept clean and in good working order. Nozzles should be replaced when they begin to show signs of wear. Pesticide application equipment comes in all shapes, sizes, types, and prices. Select equipment according to its intended use.

Hose-end Sprayer: A hose-end sprayer is a pesticide-holding bottle that has a hose attachment. Once the pesticide-holding bottle is attached to a hose and the water is turned on, the pesticide is dispensed at a particular ratio as the water flows out of the garden hose; this occurs due to a phenomenon called the venture principal in which passing water through a pipe creates a suction. These devices, also suited to dispensing fertilizer solution, are inexpensive and serve the purpose

quite adequately. However, one is required to calculate the appropriate ratio of pesticide to water to add to the bottle so that the solution that is sprayed has the correct concentration. An adjustable nozzle is a desirable feature. An antisiphon device should be part of a hose-end sprayer because if there is drop in your water pressure, the chemicals can be sucked up into your water system. The extra price you may have to pay for this safety feature will be well worth the peace of mind.

Compressed-air Sprayer (backpack or tank sprayer): A pesticide is mixed in a small tank (generally 1 to 5 gallons). The tank is carried like a backpack, riding on your back and supported by the shoulders. A hand-operated pump supplies pressure during application. A single nozzle releases the spray at the end of a hand-held wand. The applicator has excellent control over coverage, making this sprayer a good choice for treating dwarf fruit trees, vegetables, and ornamentals. However, the spray will only reach a few feet beyond the length of your arm, and therefore back pack sprayers are not effective for controlling pests at heights more than 10 feet or so. Pesticides with a wettable powder formulation are difficult to apply with this type of equipment because such a spray mixture requires agitation. As water weighs more than 8 lbs. per gallon, small tanks are easier to carry than large tanks.

Hand Duster: The duster may consist of a squeeze tube or shaker, a plunger that slides through a tube, or a fan powered by a hand crank. Uniform coverage of foliage is difficult to achieve with many dusters. Dusts are more subject to drift than liquid formulations due to their light weight and poor sticking qualities. Many dust formulations are sold in dispenser canisters.

Watering Equipment

Watering is an essential garden job for most gardeners. An adequate water supply makes a big difference in vegetable garden yields and landscape plantings (especially for recent plantings). The purchase of watering equipment depends on available facilities, water supply, climate, and garden practices. If there is no outdoor spigot near the garden, the expense of having one installed may be greater than the benefits gained except in very drought-prone areas, or in the case of a gardener who is fully dependent on the season's produce. Where rainfall is adequate except for a few periods in the summer, keeping watering equipment simple is a wise decision; a garden hose with a fan-type sprinkler will suffice. A water breaker for small seedlings is useful. But, in areas where there are extended periods of hot weather without precipitation, the local water supply is likely to be short. Overhead sprinklers waste water, so in this case, a drip irrigation system may be in order. Drip irrigation puts water right at the roots and doesn't wet plant leaves, helping to prevent disease. Timers are available that allow automatic watering with drip and some other systems. However, this type of system is relatively expensive and may be considered a nuisance by some gardeners because of maintenance and placement requirements. Cultural practices, such as mulching, close plant spacing, shading, or wide-bed planting, will significantly reduce water needs.

Soil Monitoring Equipment

Soil test kits can be purchased in various capabilities and levels of sophistication. Kits include chemicals and methodologies for measuring soil pH and nitrogen (N), phosphorus (P), and potassium (K). These are handy, but not always necessary. Depending on your gardening practices, soil testing once every two to three years is adequate. Garden soil tests are offered through the Extension offices or private labs; results from these testing services are often preferable compared to home kits because lab results are likely to be more accurate than with the kits. Some gardeners like to monitor the soil pH and nutrient content frequently though, making a soil test kit a worthwhile purchase. Electronic pH testers are on the market for those who wish to track changes in soil pH over time.

Soil Thermometer: Soil temperature is critical for many vegetable and food crops. Soil thermometers measure soil temperature and the internal temperature of a compost pile. Seeds planted in soil that is too cold will often rot and seedlings planted in cold soil will delay growth until the ground temperature gets warmer and will likely result in stunted plants. A soil thermometer will assist the gardener in determining the proper time to plant seeds and seedlings. Optimal soil temperatures for seeds of early vegetables are between 45° and 50° F and 50° to 55° F for seedlings. Soil temperatures for warm weather species should be at least 65° F.

Other Environmental Monitoring Equipment: Serious gardeners often invest in various types of equipment that allow them to monitor the microclimate around the garden or indoors. A rain gauge is an inexpensive device that helps the gardener determine if enough rain has fallen for garden plants. A minimum-maximum thermometer is a useful, device to measure nightly lows and daytime highs within an area; these are especially valuable in a greenhouse. Light and watering meters can be purchased for indoor plant monitoring.

Other Equipment

Seeding and Planting Tools

Depending on the size of your garden and your physical abilities, you may want to consider a row seeder. Seeders with wheels make easy work of sowing long rows of corn, beans, or other vegetables. Seeders are available which make a furrow, drop the seeds properly spaced, and close up the furrow behind the seed, all in one pass. They do not perform quite as well on small-seeded crops, and the effort of setting up a seeder for small areas is more than that expended in hand seeding. A hand-held seeder is probably a better choice for this type of work. Broadcast seeders are available for sowing seeds such as rye or wheat for a cover crop, but are generally not necessary for the average home gardener since broadcasting is easily done by hand once the proper technique is learned.

Trellises/Cages

Trellises and cages for vining plants save space and keep fruits off the ground, reducing damage to plants and the amount of stooping required for harvest. Look for heavy-duty materials and a sturdy design that will stand up to rain, wind, and drying. Wire should be of a heavy gauge, and wood should be treated with non-phytotoxic (i.e., not toxic to plants) materials. Metal parts should be rustproof or at least rust-resistant. If you build your own, you will probably save a considerable amount of money and get better quality for the price.

Composting Equipment

If you wish to make compost regularly, compost bins in some form may be helpful. You can construct two bins out of planks or concrete blocks. Make the bins about four feet high, four feet wide, as long as desired, and open at one end for easy access. Leave spaces between blocks or planks for aeration. Plant refuse may be accumulated in one bin while the composting process is taking place in the other. A third bin may be desirable for nearly finished or finished compost storage. A simple, portable compost bin can be made with three or four sturdy used pallets that are simply stood on their ends in a square or open square and lashed or otherwise held together. This type of bin can be disassembled for easy turning and emptying, then reassembled around the new pile. A chicken wire cage supported by three or four wooden stakes will also work satisfactorily, but is somewhat less sturdy. There are also ready-made and kit composters available, including slat-sided cylinders into which refuse is added from above and compost removed at ground level. Rotating barrels for easy turning are also available; gardeners who have physical disabilities may find either of these types easier to deal with than the standard compost bin. Whichever type of compost maker you use, make use of the nutrients that leach out from under the pile. This is easily done by locating the composter in the garden (which also reduces hauling time), or under a large tree, or by making some provision to catch the runoff from the pile and use it as liquid fertilizer.

Season Extenders

Your annual harvest can be greatly increased by extending the growing season, starting earlier in the spring and harvesting past frost. (See *Season Extenders*, Virginia Cooperative Extension publication 426-381.)

Harvesting Equipment

Harvesting equipment varies depending on the size and type of garden, whether or not food is to be stored, and the way in which it is to be processed. Baskets are useful to most gardeners. They may be purchased at garden or farm supply stores or sometimes may be given to you at no cost from local grocery stores or fruit stands. Berry baskets for small fruits, baskets with handles for

carrying vegetables, and peck or bushel baskets for storage are all useful. Fruit pickers are nice and easy to use for tall fruit trees. A sharp knife for cutting vegetables off plants is handy and helps prevent plant damage.

Food processing equipment includes canners, blanchers, dehydrators, and sealers for frozen food packages. There is even a home vacuum-packer available. A food mill is inexpensive and very useful for making sauces and juices; a blender or food processor is also useful to the gardener with extra food. More specialized tools include corn cutters which remove kernels from the cob, bean frenchers and shellers, cherry pitters, strawberry cappers, apple corers and peelers, jelly strainers and thermometers, and many more. For canning, a large kettle or pot is indispensable for preparing food prior to canning. A jar lifter will prevent burned fingers; a funnel for transferring food to jars reduces messiness. As always, choices depend on individual needs.

Purchasing and Maintaining Tools

When purchasing tools, buy for quality rather than quantity. Your tools will be in frequent use throughout the garden season. Cheap tools tend to break or dull easily and may end up making a job unnecessarily difficult and frustrating. Also, consider the cost and effort in replacing a cheap tool. Quality tools will last and tend to increase in value with time if well kept. Tools should be lightweight for easy handling, but heavy enough to do the job properly. Metal parts should be of steel, which will stay sharp, keep its shape, and outlast softer metals. Handle quality is just as important as the working end (e.g., blade) quality. Consumers' magazines and gardening publications frequently have articles explaining what to look for in tools and listing alternatives to local hardware stores, which often carry a single line of tools. Several excellent books featuring garden tools have been published and may be available at a bookstore, library, or through inter-library loan.

Keeping a tool clean and sharp will increase its usefulness and lengthen its life. Learn the techniques of sharpening each tool, and practice them frequently. Professional gardeners frequently sharpen their tools (at least daily). Clean your tools after each use and oil the blades.

The last step in tool care is to put tools in their proper places. Tools left in the garden will rust and break and can be a safety hazard. Some gardeners paint handles with a bright color to make their tools easy to spot. And, if each tool has its own place in the storage area, it is simple to determine if tools are missing before closing up for the day.

Before winter sets in, sharpen tools, then coat metal parts lightly with oil and rub wooden handles with boiled linseed oil. Drain power tools of gasoline, and obtain filters, mufflers, and tune-up parts so a fall or late-winter tune-up can get the machine ready for early spring jobs. Have maintenance done, if needed, in the winter, when demand is lowest and you can afford to let the repairer take his or her time.

In fall, any trellises or cages that have been outdoors should be cleaned and stored inside if possible. Traps and other pest control devices should also be stored if the pest season is over. Cold frames and other season extenders should be protected from damage by ice and snow or high winds, and once their job is done, should be repaired if necessary and put away if possible. Tools with wheels, like cultivators, seeders, and carts, should be oiled and stored.

Thoughtfully selected and cared for, your tools will give many years of service. This extra help in the garden will pay for itself in time.

This publication was originally authored by Diane Relf, Extension horticulturist (retired).

Farm Tools

PINCERS PUL
AND
TURNERS
BANGERS HANGERS
AND
STRAIGHTENERS

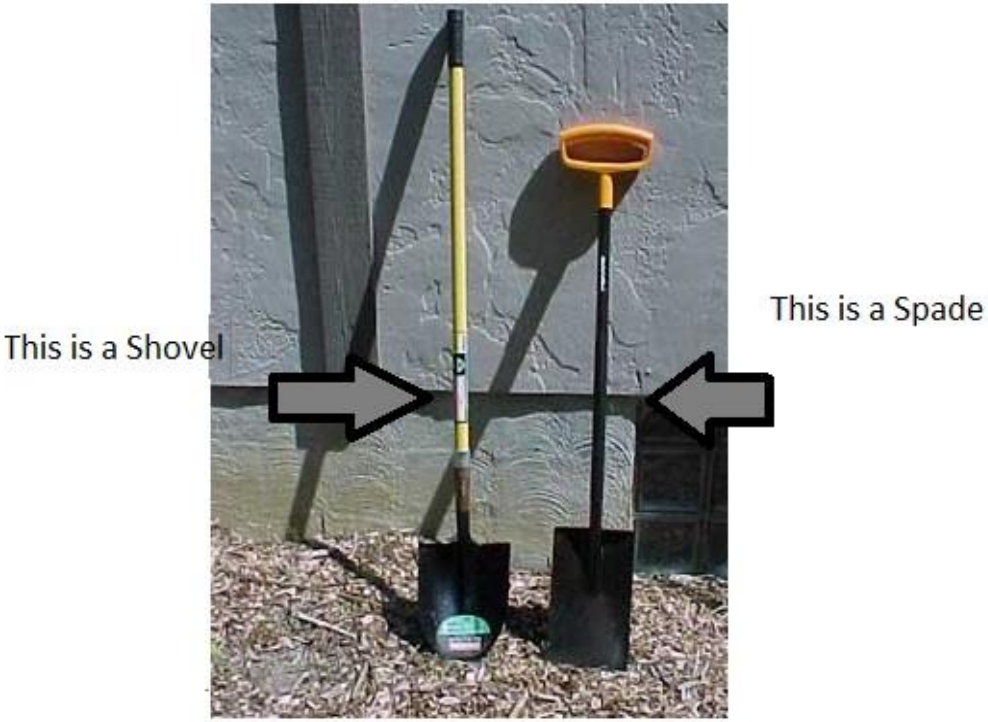
Learning Objectives

- Identify various tools by name
- Become familiar with safety measures required for each tool
- Learn about the proper technique for using each tool as well as their various uses
- Understand maintenance of each of these tools

Hand Tools in the Garden

- Shovel vs. Spade
  - A shovel is a basic digging tool with various head shapes depending on its use. The shovel head always comes to a point.
  - A spade is similar to a shovel but has a square head. They are often favored for digging shallow holes as well as moving around loose material.

[more on shovels, spades, & shoveling]



- Trowel
  - a one-handed tool that resembles the shovel and spade. Due to its size, the trowel is favored when making more detailed/precise holes in the soil. Trowels are most used for transplanting or planting seeds in a garden.

- Hoe
  - This tool has a longer neck but a small head with various shapes depending on its use. The hoe is a common tool in gardening for making very shallow holes or even lanes in the soil as well as leveling out the ground and uprooting weeds.

Collinear Hoe: narrow blade used for slicing weeds

Scuffle/Stirrup Hoe: Blade cuts through tough weeds fast and in both directions

Standard Garden Hoe: average hoe used for various tasks

Dutch Hoe : blade designed to push/pull weeds just below the surface

Loop Hoe

- Rake

Rakes are used to comb the top of your garden and pick up loose material. The garden rake's "teeth" can dig into the ground to pull up loose material, moving around mulch and removing weeds. The leaf rake gently moves lighter materials to the desired locations.

Garden Rake

Lawn Rake
OR
Leaf Rake

Garden/Gravel Rake

Lawn or Leaf Rake

- Cultivator
  - similar to the rake, a cultivator has thick metal “teeth” that can pull up loose top soil and other material. Digs deeper into the ground than rake so does not drag leaves/mulch/weeds as well.

Hand Cultivator

Mobile Cultivator

Hand Mattock

Pruning Tools

Used to cut or prune plants and trees

Pruner

Folding hand saw

Shears or loppers

[Tree Pruning Tools]

Wheelbarrow

- Used to move material from one place to another

Garden Hand Tool Safety

- Using many of these tools can be strenuous work and can cause back pain, make sure to take breaks and stretch periodically.
- Check the terrain you are working with is clear of wires and underground cables/pipes.
- Wear sturdy close-toed shoes as well as gloves to prevent hot spots and blisters from forming.
- Consider wearing long pants to cover the skin completely.

Garden Tool Maintenance

There are many tasks that require your attention in a garden, so there will be times when you need to put down your tools. When doing so:

- Place the tool in plain sight and tell those around you where you left it.
- If you have something to lean it up against, do so with the metal edge facing away. This prevents someone stepping on the tool and getting hurt.
- Although most of the above tools can handle rain or a single storm, long term exposure will damage your tools. So it is better to properly store them in the first place rather than leave them out overnight.

Garden Maintenance

- Long-term storage
  - Have your garden tools organized (by type or use) and stored in a place that protects from the weather.
  - Tool racks in sheds or garages are often used. Here's another idea!

Cleaning & Sharpening

- Removal of debris
  - It is important to remove any dirt or debris that you may have collected while working with the tools. This prevents wear and other damage to the tool.
- Examining the tool
  - Look over your tool and pay attention when using it to evaluate its quality. You can often feel when a tool is not performing as well as it should, this is a sign that either maintenance needs to be done or you may need a new tool.
- Sharpening edges
  - Whetstones: small rectangular stone used for small blades and edges
  - Dremel: an electric handheld device with a variety of head attachments that are useful for sharpening complicated edges and groves (i.e. saws, mower blades)
  - Bench sharpening: a composite wheel that rotates at high speeds (adjustable) and has a number of coarseness levels and wheel types.

Field-Scale Implements

- Used on larger plots of crops.
- Replaces the work done by horses, humans, or other animals.
- These machines can till soil, plant seed, harvest, thresh grain, bale hay, move and remove items—eliminating some back-breaking work for farmers.
- The key is to know when to use them, how to use them, and how to fix them when they break down.

Field-Scale Implements

- Tractors
- Manure spreaders
- Cultivators
- Tillers
- No-till seeders

Tractors

- Serves multiple purposes which include plowing, tilling, discing, harrowing, and planting. Maximizes output, minimizes labor- can play an important role on a small farm if the operation is large enough to justify its use

Walk Behind Tractor

- This tool can be utilized in a variety of different ways including tilling, mowing, and cultivating , with lower fuel use than a full size tractor [walk behind tractor in action]

Manure spreader

Evenly distributes manure for proper fertilization of crops.

restoring an old horse drawn manure spreader

new small manure spreader

Tiller (rotary hoe)

- Tilling is the process of preparing the soil for planting by agitating it and opening it up.
- Machines like the ones shown here move the soil, level it, and remove old plants.
- Power take-off (PTO) required to operate tractor drawn models

Walk behind

Tractor drawn

No-till seeder

- Tilling can often disturb the soil too much, which decreases moisture, nutrients and causes erosion.
- No till planting uses seeders like these to place the seed in the soil without opening it up too much.

Cultivator

- Stirs up and moves the soil around.
- It is used before planting to aerate the soil or carefully, once the plants are in place, to take out weeds.

Wheel Disc Cultivator

- After soil has been initially worked up, wheel shaped discs are used to further break up and aerate the soil
- Like most other field-scale machines it can be either horse-drawn or tractor pulled

Discing a Garden

Livestock Tools & Equipment

- Halters
- Stanchions
- Chicken Coops
- Animal Care Tools
- Hay Handling
- Fencing Tools

Halters

- Used to lead or tie up an animal.
- Halters circle around the nose→under the chin →behind the ears, then fastened to a rope or chain to lead.

Stanchions

- Vertical structures built to hold animals in place during milking or veterinary care
- A feeding trough is placed in front of them so they can eat while being milked.

Movable chicken coop (chicken tractor)

- A house for female chickens to protect them from bad weather and predators.
- This coop has an open-air patio so the hens can get some fresh air to stay healthy when weather permits.
- Wheels make it a mobile home.

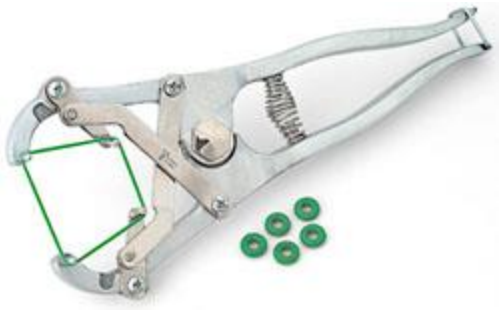
Animal Care Tools

- Hoof trimmers & hoof pick
  - Hoof care important to hoof health

Goat or sheep hoof trimmer

Picking out a horse's feet

- Castration & tail docking
  - Bloodless elastrator can Be used when animal is young



Hay handling

Large round bale stacker

Large bale spear

Hay elevator makes loading small square bales of hay in the loft easy!

Making Small Square Bales

Fencing Tools

Post hole digger

Comealong

Crimp tool

Homemade fence stretcher

Fencing tool

[Field Fence Installation Part 1]

[Field Fence Installation Part 2]

Self-Review Questions

- Why is it important to properly store tools when they are not being used?
- Why is a well-maintained tool safer than a rusty, dirty, or dull edged tool?
- Which tools are best for weeding?

FISKARS

www.fiskars.com

FISKARS QUALITY SINCE 1649

Pick up a Fiskars product and sense its ergonomic design and innovative functionality. Quality dictates everything Fiskars does, a standard enshrined in the company's core values since its inception in 1649.

In that year, Peter Thorwöste was granted permission to manufacture cast iron and forged products in a small Finnish village called Fiskars. Today as one of the Western world's oldest companies, Fiskars has grown into a multinational corporation, present in more than 40 countries on four continents and is the number one in hand operated garden tools in North America, Australia and much of Europe.

It's true that the company has come a long way but Fiskars' roots and soul continue onwards in Fiskars village, where, some 10 kilometers away many of our garden tools are still manufactured to this day, continuing the same stringent quality standards.

Fiskars ergonomic, lightweight, yet powerful garden tools are designed to reduce strain and fatigue, and to ensure gardening is a pleasure, which is what gardening should be about. We're confident that our customers recognize this and continue to support our aspirations for enduring quality.

Our Quality Pledge

When properly used and maintained, Fiskars garden tools shall remain free of defects in material and workmanship. Any exception to the rule will simply be repaired, replaced or substituted by a product of equal value. Replacement tools or spare parts are offered when returning the tool to the retailer, or contacting the local customer service department.

NEW PRODUCTS
NEW INNOVATIONS

NEW

FISKARS SINGLESTEP™

The new additions to the SingleStep™ range of cutting tools offers a great selection for anybody starting out in the garden.

SingleStep™ Lopper Bypass Hook head (S) L28 112160 **p. 57**

SingleStep™ Lopper Bypass Hook Head (L) L38 112460 **p. 57**

SingleStep™ Lopper Anvil Hook Head (L) L39 112450 **p. 57**

SingleStep™ Hedge Shear Wavy Blade HS22 114730 **p. 64**

FISKARS SMARTFIT™

This new SmartFit™ pruner is a neat fit in the hand and can be used for varied cutting tasks.

SmartFit™ Pruner Bypass P68 111610 **p. 39**
This multi-purpose pruner with adjustable cutting aperture is the perfect pruner for convenient and ergonomic cutting.

FISKARS QUIKFIT™

Excellent extensions to the versatile QuikFit™ range of interchangeable heads and shafts. Enables gardeners to swiftly change between activities in the garden and yard.

QuikFit™ Flower Rake 135552 **p. 83**
A neat and handy addition to the QuikFit range for detail work in garden beds.

QuikFit™ Gutter Cleaner 135542 **p. 84**
Introducing a great handy device for all blocked and dirty gutters

QuikFit™ Yard Broom 135532 **p. 84**
An excellent all round broom head for the yard or garden.

QuikFit™ Patio Broom 135533 **p. 84**
A purpose-made broom head for a clean sweep on all patios and smooth surfaces in the garden.

QuikFit™ Sweeping Broom 135534 **p. 85**
A modern revision of the traditional sweeping broom.

QuikFit™ Tree Cutter 136525 **p. 85**
The new QuikFit™ tree cutter can be used in combination with any QuikFit™ telescopic shaft for a new dimension in tree pruning.

FISKARS QUANTUM™

Introducing an innovative premium quality range of cutting tools for demanding gardeners.

Quantum™ Pruner Bypass P100 111970 **p. 37**

Quantum™ Lopper Bypass Scissor Head (S) L102 112240 **p. 51**

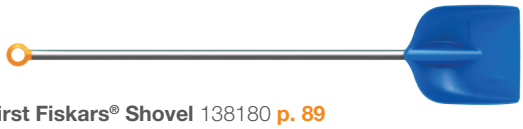
Quantum™ Lopper Bypass (M) L104 112330 **p. 51**
Quantum™ Lopper Bypass (L) L108 112630 **p. 51**

Quantum™ Lopper Anvil (L) L109 112610 **p. 51**

Quantum™ Hedge Shear HS102 114820 **p. 63**

MY FIRST FISKARS®

Introducing a solid selection of newly revised working tools for small hands and big minds.



My First Fiskars® Shovel 138180 **p. 89**

My First Fiskars® Spade 138170 **p. 89**

My First Fiskars® Rake 138160 **p. 89**

My First Fiskars® Broom 138150 **p. 89**

My First Fiskars® Box Set 138200 **p. 89**
The new box set offers an innovative selection of tools for young children to get out and explore their world.

PICTOGRAMS

Level of enhancement

EaseCut™
Indicates by how many times the cutting power is multiplied.

Fiskars USPs

FiberComp™
Strong, durable and lightweight properties.

SoftGrip™
Comfortable anti-shock handle.

PowerClean™
Combination of soft and hard bristles.

TruEdge™
Mechanically strong, sharp, corrosion-resistant an non- stick blade coating.

TruGrip™
Comfortable organic handle.

Cutting capacity
Shows the maximum cutting diameter.

Micro tip
Thin and sharp blades for precision cutting.

Safety
Loop helps to shield fingers when cutting.

Female
For female use.

Power tip
Cutting power is distributed evenly.

Shock-proofed
Improves comfort by absorbing vibrations.

Fingerloop handle
Prevents slipping and protects fingers.

Male
For male use.

Telescopic
The length of the product can be adjusted.

Push and pull blade
For faster, more efficient cutting.

Pull blade
Optimised for pruning green wood.

Hand size
Suitable for small hands.

Strength
Withstands hard wear and loads.

Tightly sealed
Shaft and blade are fused together for a tight seal.

Weather proof
Withstands all types of weather.

Ambidextrous
For both right-handed and left-handed use.

Pocket-sized
Fits easily into a pocket.

Belt holder
Optimised feature for convenient portability.

Center of gravity
Perfectly balanced.

Right-handed product
For right-handed use.

Product Materials

Aluminium
Lightweight, strong properties.

CrMov
Highly durable material which holds an edge.

PBT
Lightweight, flexible and durable.

Boron steel
Sharp and durable.

Stainless steel
Mechanically strong and corrosion-resistant.

PTFE coating
Corrosion-re-sistant, non-stick blade coating.

Steel gear mechanism
Strong and effective steel mechanism.

Genuine leather
Made of tough, genuine leather.

Usage

For fresh wood
Bypass cutting action.

For dry wood
Anvil cutting action.

For universal cutting
For cutting thin steel plates,plastic, tube, rope, etc.

Hook head
For heavy cutting of green wood.

Scissor head
For precision cutting of green wood.

Fine toothing
For efficient sawing of planks and boards.

Efficient toothing
For sawing green wood.

Splitting axe
For easier, faster splitting of wood.

Chopping axe
For easy cutting through fresh wood.

Brush hook
For trimming undergrowth and even clearing small trees.

Snow tool
For clearing snow in small or large areas.

Fruit picking
For harvesting fruit trees.

Yard cleaning
For clearing debris from yard areas.

Patio cleaning
Optimised for clearing finer-particle debris.

Gutter cleaning
For easy reach and clearing of gutter debris.

Flower stems
For cutting flower stems.

Hedges and bushes
For cutting hedges and bushes.

Grass
For cutting grass.

Potted plants
For cutting potted plants.

Bonsai plants
For cutting bonsai plants.

Herbs
For cutting of delicate herbs.

Sharpening
wooden canes

Carving
For stripping bark.

Pruning/Grafting
For cutting of small side shoots, laterals and pruning of weak growth.

Grafting
For various grafting tasks.

Whittling
For whittling wood.

Cotton & string
For cutting cotton and string.

Building site
For cutting rockwool and fiberboard.

Vegetables
For cutting and processing vegetables and mushrooms.

Fish
For preparing fish.

Soil care
For all soil-related tasks.

Lawn care

Paving

Leaf collecting

Digging
Preparing planting holes and removing sod or soil.

Garden digging
Slicing and cutting grass tufts and moving and mixing soil.

Construction
digging
Heavy-duty digging.

Sandmoving

Composting

Haying

Axe
sharpening
For maintaining optimal sharpness of Fiskars axes.

Knife
sharpening
For optimal sharpening of Fiskars knives.

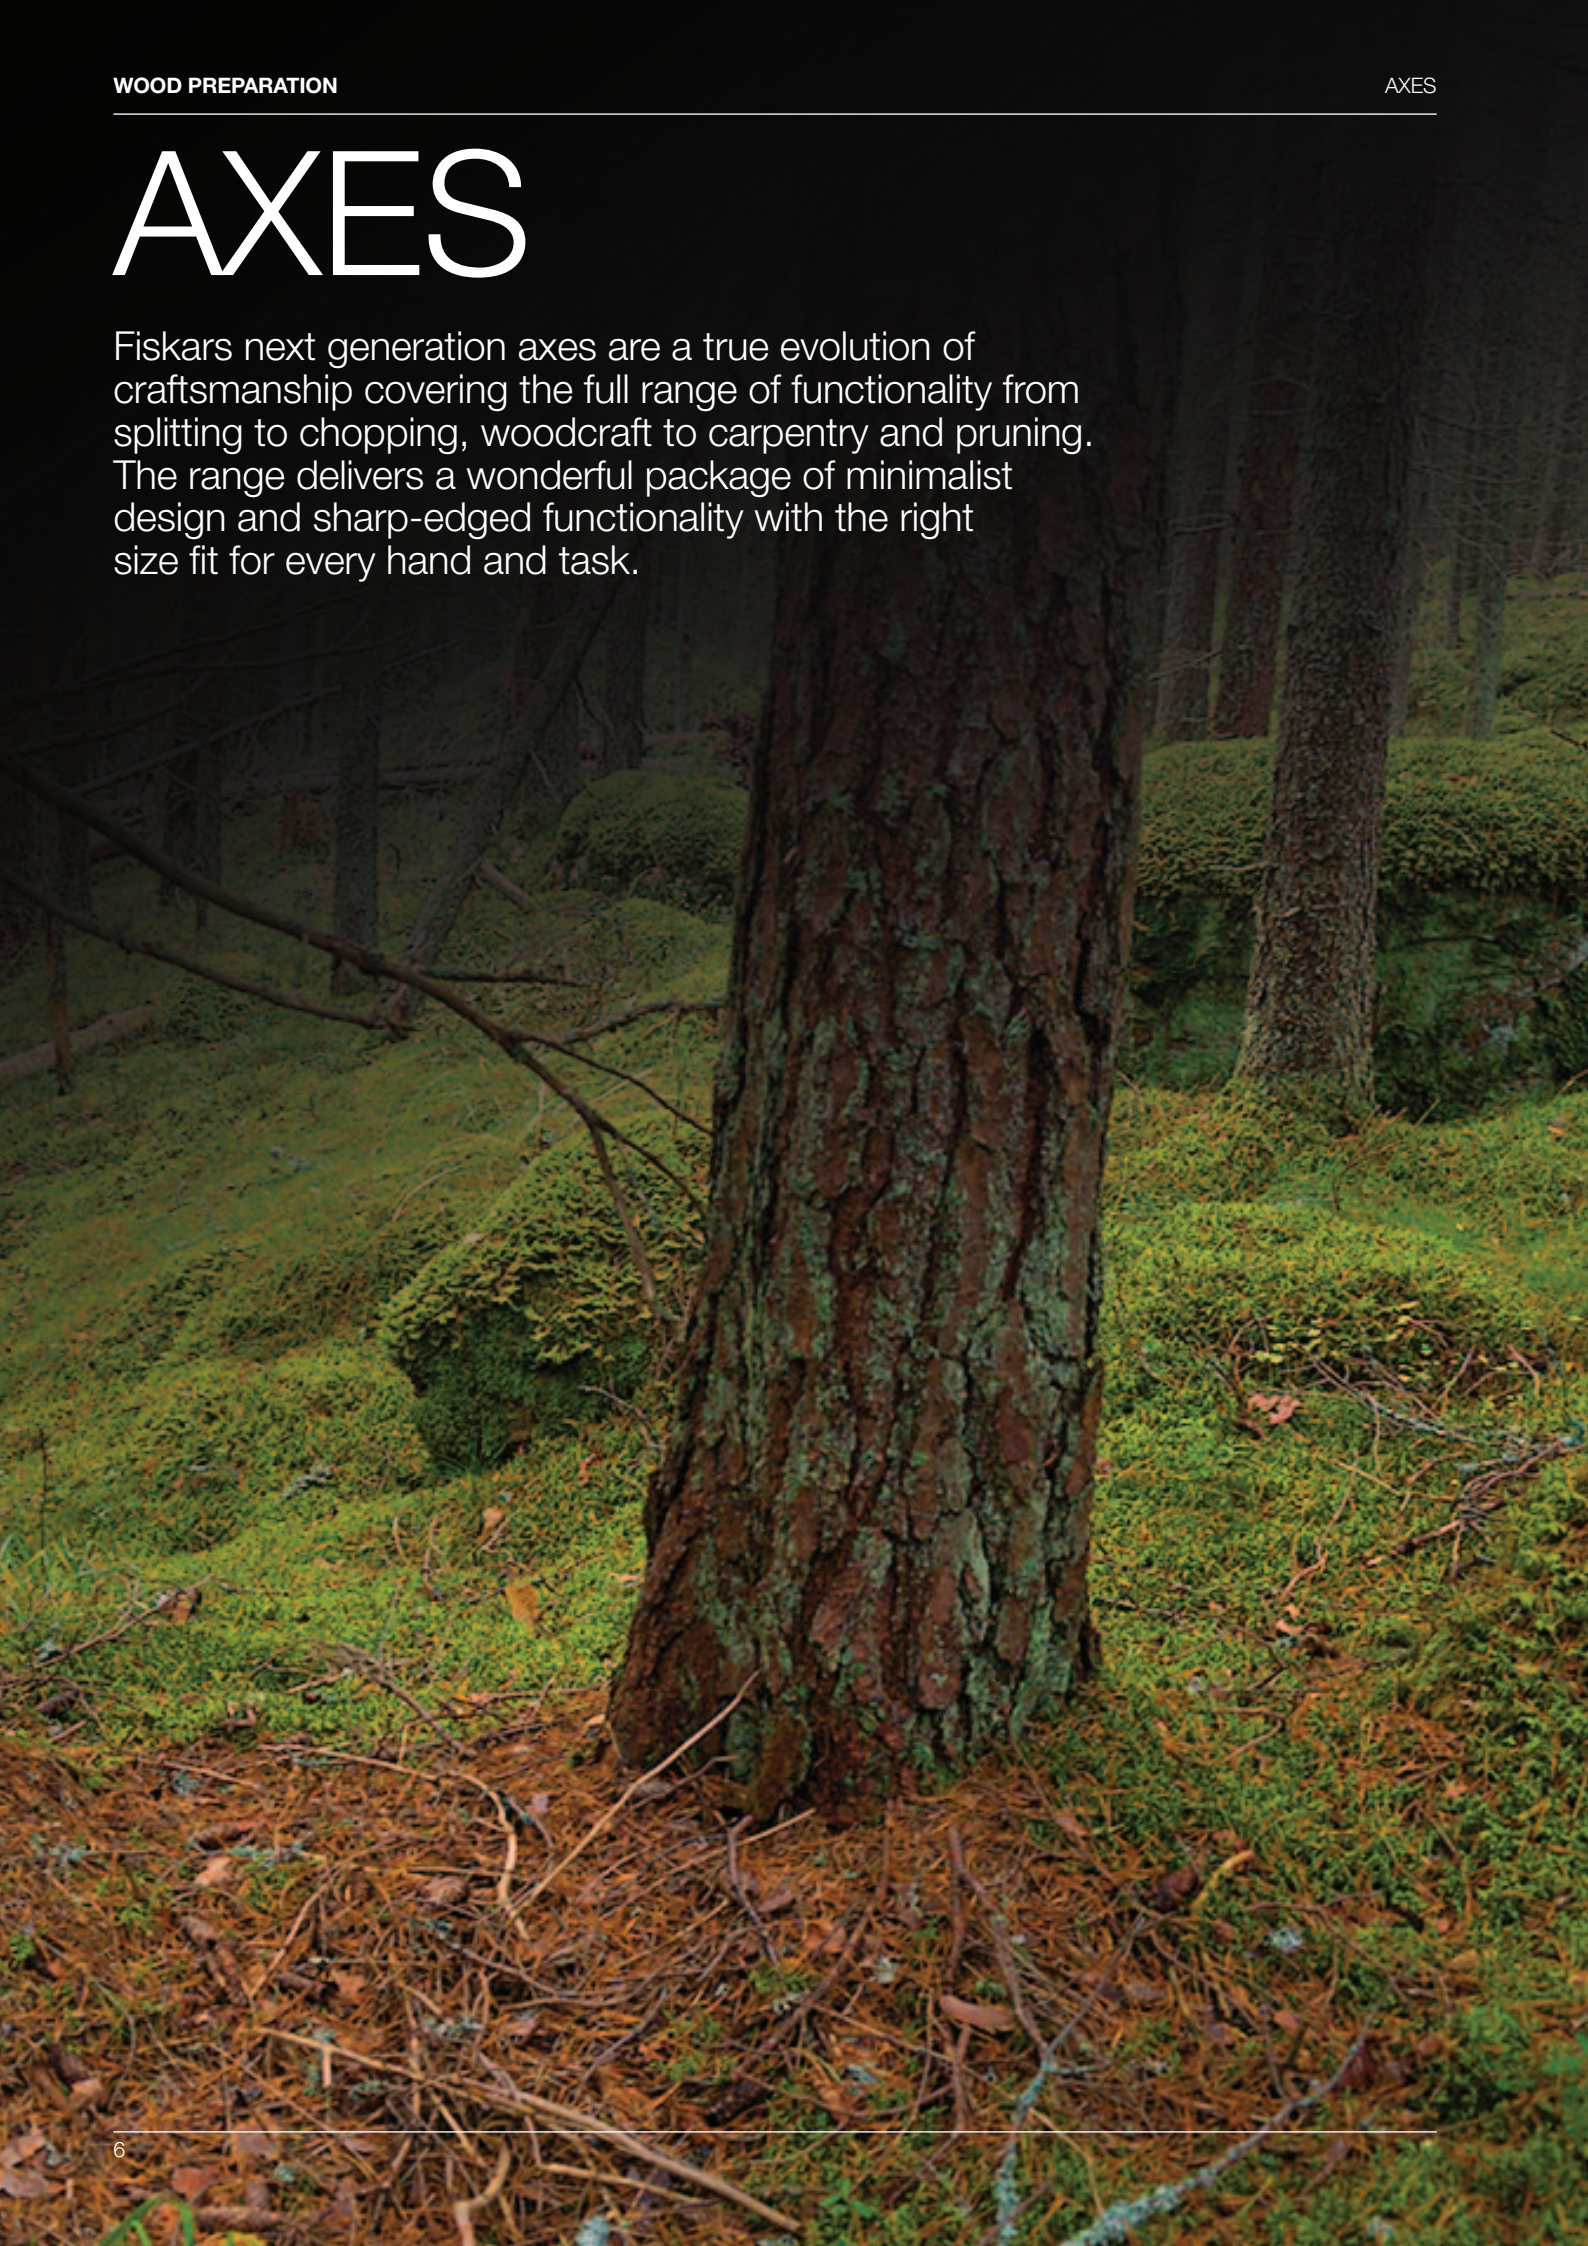
Usage and maintenance

Spare parts
Spare parts are available.

Plus parts
Can be complemented with additional parts.

AXES

Fiskars next generation axes are a true evolution of craftsmanship covering the full range of functionality from splitting to chopping, woodcraft to carpentry and pruning. The range delivers a wonderful package of minimalist design and sharp-edged functionality with the right size fit for every hand and task.



Chopping Axes

Camping Axe X5	Article No 121121	Product benefits

- < Ideal for camping and other outdoor activities
- < A small, light axe that can be easily carried in your bag or on your belt
- < Perfect balance between the head and shaft for the most safe, comfortable and efficient use
- < Ultra light and durable FiberComp™ handle minimises fatigue and makes the axe virtually unbreakable
- < Optimal anti shock surface structure ensures a comfortable, firm grip
- < Hooked end of the handle prevents the axe from slipping
- < With canvas sheath
- < Retail box: 4
- < Length: 228mm
- < Weight: 480g

Chopping Axe X7	Article No 121420	Product benefits

- < For universal cutting tasks: for campers, hikers, outdoor activities as well as practical for the car or boat
- < Perfect balance between the head and shaft for the most safe, comfortable and efficient use
- < Ultra light and durable FiberComp™ handle minimises fatigue and makes the axe virtually unbreakable
- < Optimal anti shock surface structure ensures a comfortable, firm grip
- < Hooked end of the handle prevents the axe from slipping
- < With plastic sheath for easy carrying and storage
- < Retail box: 4
- < Length: 355mm
- < Weight: 640g

reddot

6 411501 214201

Carpenters Axe X10	Article No 121440	Product benefits

- < Specially designed for carpenters and construction workers
- < 30 degree cutting bevel angle for chopping axes
- < Perfect balance between the head and shaft for the most safe, comfortable and efficient use
- < Ultra light and durable FiberComp™ handle minimises fatigue and makes the axe virtually unbreakable
- < Optimal anti shock surface structure ensures a comfortable, firm grip
- < Hooked end of the handle prevents the axe from slipping
- < With plastic sheath for easy carrying and storage
- < Retail box: 4
- < Length: 440mm
- < Weight: 980g

reddot

6 411501 214409

Chopping Axe X15	Article No 121460	Product benefits

- Specially designed for forestry work: broad but slim profiled blade ideal for cutting live branches and tree limbs
- 30 degree cutting bevel angle for chopping axes
- Perfect balance between the head and shaft for the most safe, comfortable and efficient use
- Ultra light and durable FiberComp™ handle minimises fatigue and makes the axe virtually unbreakable
- Optimal anti shock surface structure ensures a comfortable, firm grip
- Hooked end of the handle prevents the axe from slipping
- With plastic sheath for easy carrying and storage
- Retail box: 4
- Length: 599mm
- Weight: 1520g

reddot

6 411501 214607

Splitting Axes

Splitting Axe X11	Article No 122440	Product benefits

- For splitting small logs and chopping firewood
- 35 degree convex cutting bevel angle for splitting axes
- The convex shape strengthens the edge to make it less sensitive to fracture
- Perfect balance between the head and shaft for the most safe, comfortable and efficient use
- Ultra light and durable FiberComp™ handle minimises fatigue and makes the axe virtually unbreakable
- Optimal anti shock surface structure ensures a comfortable, firm grip
- Hooked end of the handle prevents the axe from slipping
- With plastic sheath for easy carrying and storage
- Specially designed for forestry work
- Retail box: 4
- Length: 443mm
- Weight:1075g

reddot

6 411501 224408

Splitting Axe X17	Article No 122460	Product benefits

- For splitting large logs
- 35 degree convex cutting bevel angle for splitting axes - the convex shape strengthens the edge to make it less sensitive to fracture
- Perfect balance between the head and shaft for the most safe, comfortable and efficient use
- Ultra light and durable FiberComp™ handle minimises fatigue and makes the axe virtually unbreakable
- Optimal anti shock surface structure ensures a comfortable, firm grip
- Hooked end of the handle prevents the axe from slipping
- With plastic sheath for easy carrying and storage
- Retail box: 2
- Length: 722mm
- Weight:1570g

SAWS

Fiskars saws have teeth designed especially for wood. Prune branches and clear foliage in difficult positions safely with a lightweight saw. The new Fiskars Xtract™ range features a unique retractable mechanism with integrated belt clip making them safe to carry and easy to store.

Saws

Xtract™ Garden Saw (L) SW75

Article No 123880

Product benefits

- Efficiently saws fresh wood
- New design with handy belt clip which retracts when in use
- SoftGrip™ handle ensures a safe grip
- Finger guard protects fingers from sliding onto the blade
- Blade length 255 mm
- Large cutting capacity up to 220mm
- Cuts on the pull stroke
- Retail box: 4
- Length: 330mm
- Weight: 230g

reddot design award winner 2012

KNIVES

Fiskars designs perfect knives for a range of smaller gardening applications. Their hard wearing blades are made from stainless and carbon steel to ensure years of trouble free operation.

Knives

Utility Knife K40

Article No 125860

Product benefits

- General purpose knife with plastic sheath
- Ergonomically designed plastic handle with finger guard
- Blade of stainless steel. Length 100mm
- Retail box: 4
- Length: 218mm
- Weight: 70g

Design Zentrum Nordrhein Westfalen Design-Innovation

6 411502 870628

Hooked Grafting Knife K62

Article No 125880

Product benefits

- For taking cuttings, picking flowers and vegetables and cutting laterals
- Handle of recycled plastic attached with a brass rivet
- Blade of stainless steel
- Retail box: 4
- Length: 170mm
- Weight: 50g

8 008220 020473

Grafting Pocket Knife K61

Article No 125890

Product benefits

- For cutting small side shoots, pruning of weak growth and picking flowers and vegetables
- Handle of recycled plastic attached with a brass rivet
- Blade of stainless steel
- Retail box: 4
- Length: 170mm
- Weight: 50g

8 008220 020480

Grafting Penknife K60

Article No 125900

Product benefits

- Ideal for grafting and making wooden canes for holding small plants and bushes
- Handle of recycled plastic attached with a brass rivet
- Blade of stainless steel
- Retail box: 4
- Length: 170mm
- Weight: 50g

8 008220 020497

Mineral Wool Knife K20

Article No 125870

Product benefits

- For cutting mineral wool
- Ergonomically designed handle with finger guard
- Blade of stainless steel
- Retail box: 4
- Length: 420mm
- Weight: 54g

6 411502 879027

FORESTRY TOOLS

Fiskars forestry tools offer a specialized package for heavy wood craft including a sledge hammer, log splitter, a selection of wedges, a brush hook for trimming and thinning as well as levers and tongs for moving logs. These durable tools are the perfect fit for effective operations and ease of use in the forest.

Forestry Tools

Brush Hook X3	Article No 126003	Product benefits

- For trimming trees and thinning out thicker branches
- Ultra light and durable FiberComp™ handle minimises fatigue and makes the tool virtually unbreakable
- Optimal anti shock surface structure ensures a comfortable, firm grip
- Hooked end of the handle prevents slipping
- With plastic sheath for easy carrying and storage
- Retail box: 4
- Length: 505mm
- Weight: 450

6 411501 260031

Log Hook	Article No 126020	Product benefits

- For lifting and moving light timber
- Use of double hooks or together with log tongs is recommended
- Hardened carbon steel with ground tip
- Handle of SoftGrip™ rubber guarantees a good grip
- Retail box: 4
- Length: 235mm
- Weight: 420g

6 411503 190008

Log Tongs	Article No 126030	Product benefits

- Hardened boron steel with ground tip
- Handle of thermoplastic rubber guarantees a good grip
- Lever mechanism with epoxy coating
- Widest grip range of 195mm
- Retail box: 4
- Length: 288mm
- Weight: 459g

6 411503 190602

Felling Lever with Turning Hook	Article No 126050	Product benefits

- Drop forged, hardened boron steel
- Forged in one piece of steel for superior strength
- Two step leverage action
- Turning hook with ground tip
- Retail box: 4
- Length: 768mm
- Weight: 1287g

6 411503 194525

Sledge Hammer

Sledge Hammer XL	Article No 120030	Product benefits

- Rounded edges on the striking surface delay burring and lessen the risk of chipping
- Rubber miss-hit guard helps to lessen jarring from miss hits
- Fibreglass core and elastomeric anti-slip and anti-vibration handle ensure greater resistance and comfort
- Hardened, tempered and forged carbon steel
- Retail box: 2
- Length: 900mm
- Weight: 5180g

6 411501 200303

Wedges

Splitting Wedge	Article No 120020	Product benefits

- Helicoidally shaped which makes the wood burst more easily therefore reducing the need to use several wedges
- Rounded head to avoid material fragmentation
- Anti return slot
- Forged steel
- Retail box: 4
- Length: 220mm
- Weight: 2200g

6 411501 200204

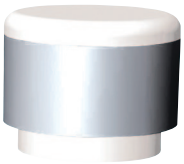
Helicoidal Splitting Wedge SAFE-T	Article No 120021	Product benefits

- Helicoidally shaped which makes the wood burst more easily therefore reducing the need to use several wedges
- Highly resistant polyamide striking surface and metal ring
- Reduces the risk of flying particles therefore no need to maintain the striking surface to remove burring
- Reduces the risk of RSI (Repetitive Strain Injury) and it dampens the vibrations when struck
- Forged steel
- Retail box: 4
- Length: 240mm
- Weight: 2400g

reddot design award

6 411501 200211

Spare Striking Surface	Article No 122151	Product benefits



- Replaceable striking surface for Helicoidal Splitting Wedge SAFE-T (120021)
- Retail box: 1
- Length: 65mm
- Weight: 300g

3 157331 221516

SPADES

Fiskars wanted to take the hard work out of digging so we've designed a range of ergonomic spades with features such as angled heads and telescopic handles that make lighter work of moving earth. Durable hardened boron steel blades are folded at the top to create a stepping surface for additional leverage. Good design, great materials and ergonomic grip make spade work a breeze.

Telescopic

Telescopic Garden Spade Pointed	Article No 131300	Product benefits

- Pointed and sharpened cutting edge to aerate, stir and turn soil and cut through roots
- Especially good for digging in stony, clay and hard soils
- Large D-shaped handle fits all hand sizes, with or without gloves
- Adjustable shaft length from 1050mm to 1250mm means the spade can be comfortably used at range of heights
- The welded connection between the blade and the shaft ensures rigid durability and longevity
- Boron steel construction adds extra strength and makes penetration into the soil easier
- Lifting angle of 13°
- Retail box: 4
- Length: 1050 - 1250mm
- Weight: 1900g

reddot design award winner 2003

6 411503 252553

Telescopic Garden Spade Rounded	Article No 131310	Product benefits

- Straight, sharpened cutting edge to aerate, stir and turn soil and cut through roots
- Large D-shaped handle fits all hand sizes, with or without gloves
- Adjustable shaft length from 1050mm to 1250mm means the spade can be comfortably used at range of heights
- The welded connection between the blade and the shaft ensures rigid durability and longevity
- Boron steel construction adds extra strength and makes penetration into the soil easier
- Lifting angle of 13°
- Retail box: 4
- Length:1050 - 1250mm
- Weight: 1950g

reddot design award winner 2003

6 411503 250559

Ergonomic

Ergonomic Garden Spade Pointed	Article No 131410	Product benefits

- Pointed, sharpened cutting edge for slicing and cutting grass tufts and moving and mixing soil
- The 17° handle angle of the handle means that the hand stays in a natural position which reduces strain on the hand and wrist
- The Y-shaped handle ensures a comfortable and firm grip
- The tear drop shaped steel shaft with a plastic coating makes it extremely durable, maximises grip and insulates against the cold
- The welded connection between the blade and the shaft ensures rigid durability
- Boron steel construction adds extra strength and makes penetration into the soil easier
- Lifting angle of 26°
- Retail box: 4
- Length: 1250mm
- Weight: 1870g

5 905568 020024

Ergonomic Garden Spade Rounded	Article No 131400	Product benefits

- Weight: 1350g

5 905568 800152

FORKS

Fiskars forks are ergonomically designed to rest comfortably in your hand when you're digging or turning over compost.

Telescopic

Telescopic Garden Fork	Article No 133320	Product benefits

- 4 sharp and firm prongs especially useful for hard and stony soil
- The adjustable shaft length from 1050mm to 1250mm means the spade can be comfortably used at a range of heights
- Large D shaped handle fits all hand sizes, with or without gloves
- Boron steel prongs add extra strength and make penetration into the soil easier
- Lifting angle of 13°
- Retail box:4
- Length:1058-1256mm
- Weight: 1800g

reddot design award winner 2003

6 411503 352550

Ergonomic

Ergonomic Garden Fork	Article No 133400	Product benefits

- For breaking down soil after digging and for moving crops and plants and bulky material (e.g leaves)
- The 17° angle of the handle means that the hand remains in a natural position, helping to reduce strain on the hand and wrist
- The Y shaped handle helps to ensure a comfortable and firm grip
- The tear drop shaped steel shaft with a plastic coating makes it extremely durable and helps to maximise the grip and insulates from the cold
- Boron steel prongs adds extra strength and makes penetration into the soil easier
- Lifting angle of 26°
- Retail box: 4
- Length: 1215mm
- Weight: 2160g

5 905568 902108

ErgoComfort

ErgoComfort Garden Fork	Article No 133422	Product benefits

- Suitable for moving garden waste and clippings
- Large D shaped handle fits all hand sizes, with or without gloves
- The rounded stainless steel shaft makes it extremely durable and rust resistant
- Boron steel prongs adds extra strength and makes penetration into the soil easier
- Lifting angle of 20°
- Retail box: 4
- Length: 1220mm
- Weight: 2100g

6 411503 312554

ErgoComfort Compost Fork	Article No 133432	Product benefits

- Long prongs for aerating compost and for twigs, potato tops etc
- Large D shaped handle fits all hand sizes, with or without gloves
- The rounded steel shaft makes it extremely durable
- Boron steel prongs adds extra strength and makes penetration into the soil easier
- Retail box: 4
- Length: 1270mm
- Weight: 1800g

6 411503 322508

ErgoComfort Manure Fork	Article No 133442	Product benefits

- Firm prongs for moving manure
- Large D shaped handle fits all hand sizes, with or without gloves
- The rounded steel shaft makes it extremely durable
- Boron steel prongs adds extra strength and makes penetration into the soil easier
- Retail box: 4
- Length: 1290mm
- Weight: 2000g

6 411503 302555

ErgoComfort Large Hay Fork	Article No 133452	Product benefits

- Wide prongs to make pitching hay easier
- Large D shaped handle fits all hand sizes, with or without gloves
- The rounded steel shaft makes it extremely durable
- Boron steel prongs adds extra strength and makes penetration into the soil easier
- Retail box: 4
- Length: 1290mm
- Weight: 1900g

6 411503 330220

Garden Light

Garden Light Garden Fork	Article No 133500	Product benefits

- Lightweight digging fork for cultivating soil.
- Large D shaped handle fits all hand sizes, with or without gloves
- The oval shaped aluminium shaft with a plastic coating makes it lightweight, resistant to rust, helps to maximise the grip and insulates from the cold
- Boron steel prongs adds extra strength and makes penetration into the soil easier
- Retail box: 5
- Length: 1130mm
- Weight: 1380g

GARDEN DRILLS

The Fiskars Garden drill is not only a useful construction tool it is also makes many everyday garden tasks simpler. It is the best tool for the job when planting flowers or bushes and also when aerating and fertilizing the ground. It comes in three sizes so you can pick the right size to suit specific garden tasks.

Fiskars QuikDrill™

QuikDrill™ Garden Drill S	Article No 134710	Product benefits

- For planting bulbs, aerating and fertilizing soil and installing small posts
- Drills a smooth edged hole without getting stuck on small stones or roots
- Handle made from FiberComp™ (a fiberglass reinforced polyamide) to make it extremely strong
- Steel tube shaft for maximum strength
- Dual cutting action with two optimally angled and sharpened blades
- Plus Parts are attached to the shaft with screws
- Working diameter 100mm
- Retail box: 2
- Length: 1100mm
- Weight: 2100g

5 905568 347107

QuikDrill™ Garden Drill M	Article No 134720	Product benefits

- For perennial planting, aerating and mixing compost and installing medium sized posts
- Drills a smooth edged hole without getting stuck on small stones or roots
- Handle made from FiberComp™ (a fiberglass reinforced polyamide) to make it extremely strong
- Steel tube shaft for maximum strength
- Dual cutting action with two optimally angled and sharpened blades
- Plus Parts are attached to the shaft with screws
- Working diameter 150mm
- Retail box: 2
- Length: 1100mm
- Weight: 2250g

5 905568 347206

QuikDrill™ Garden Drill L	Article No 134730	Product benefits

- For planting hedges and trees, drilling compost holes and installing large posts
- Drills a smooth edged hole without getting stuck on small stones or roots
- Handle made from FiberComp™ (a fiberglass reinforced polyamide) to make it extremely strong
- Steel tube shaft for maximum strength
- Dual cutting action with two optimally angled and sharpened blades
- Plus Parts are attached to the shaft with screws
- Working diameter 200mm
- Retail box: 2
- Length: 1100mm
- Weight: 2500g

PRUNERS

Fiskars pruners are ergonomically designed for comfort and ease of use and are recognised as best in category by many gardeners and industry experts for value and performance. Their ergonomic handles are made of extra durable synthetic materials and the stainless steel blades are secured by an easily accessible locking mechanism when the pruner is not in use.

PowerGear™

PowerGear™ Pruner Bypass L P94	Article No 111540	Product benefits

- Handles made from FiberComp™ to make them extremely lightweight and strong
- Unique rotating handle movement ensures that all fingers are used simultaneously and exert an equal but reduced pressure for maximum power and less effort on every cut
- Blades made from extra hard, corrosion resistant steel (CrMoV) ensuring that they stay sharper for longer
- Non stick PTFE coating on upper blade to reduce friction and make cutting and cleaning easier
- Retail box: 4
- Length: 207mm
- Weight: 272g

6 411501 965417

PowerGear™ Pruner Bypass (S-M) P92	Article No 111520	Product benefits

- Handles made from FiberComp™ to make them extremely lightweight and strong
- Unique rotating handle movement ensures that all fingers are used simultaneously and exert an equal but reduced pressure for maximum power and less effort on every cut
- Blades made from extra hard, corrosion resistant steel (CrMoV) ensuring that they stay sharper for longer
- Non stick PTFE coating on upper blade to reduce friction and make cutting and cleaning easier
- Retail box: 4
- Length: 200mm
- Weight: 192g

Two Hand Pruners

PowerLever™ Two Hand Pruner Anvil (L) P58	Article No 111620	Product benefits

- Can be used easily with one or two hands, allowing gardeners to reach further without the need to stretch uncomfortably
- Three different grip positions can be applied:
  1. Precision grip for detailed cutting
  2. Reach grip for reaching inner branches of a bush or tree crowns
  3. Power grip using 2 hands for power cutting
- The parallel handle movement helps to keep strain to a minimum on hand and arm muscles, enabling gardeners to work comfortably for longer
- Non stick PTFE coating on the upper blade to reduce friction and to make cutting and cleaning easier
- Retail box: 4
- Length: 636mm
- Weight: 475g

Maintenance

Maintenance Kit	Article No 110990	Product benefits

- Includes a maintenance guide book, diamond file and oil
- Instructions on sharpening, oiling, washing, storage etc is detailed in pictures and symbols
- Retail box:4
- Length:104 mm
- Weight:135g

6 411501 969903

Well cared for garden tools perform better and last longer. A tool can be made as good as new and ready for use again in just a few minutes. Fiskars Care Kit contains all the necessary equipment and instructions needed for maintenance of your gardening tools:

Instructions
how/when to sharpen, oil, wash, store, etc.

Diamond File
long-lasting and suitable for hardened steel

Oil
reduce friction and protect blades against corrosion

Sharpening: With time, blades become blunt and begin to lose their cutting capacity. When cutting marks are no longer tidy and strands and bark start getting stuck to the blade, it is time to sharpen the tool. Working with sharp tools benefit both the gardener and the garden: sharp tools demand less effort from the user and clean cuts promote faster healing of the plants. The easiest way to sharpen the blade is using a diamond file.

Oiling: Blades, joints and springs should be oiled on a regular basis with just a few drops of oil.

Springs: If the tool has springs, the blades should be securely locked before storage to maintain the spring tension.

SCISSORS

Fiskars orange handled scissors are design classics that have been popular for more than four decades. Our selection of garden scissors are excellent for precise cutting and trimming tasks. The carbon steel blades easily cut through materials from fine wire to flower stems.

Universal and Floral Scissors

Universal Garden Scissors 24cm S94

Article No 111050

Product benefits

- For cutting flowers and plants
- Ergonomic handles are designed based on the natural hand movement
- Handles made from impact-resistant PBT
- Extra hard stainless steel blades
- Retail box: 5
- Length: 248mm
- Weight: 142 g

PowerGear™ Steel

PowerGear™ Steel Lopper Anvil (L) L99	Article No 112480	Product benefits

- Aluminium handles maximise the power used between the blades
- Patented PowerGear™ mechanism makes the cutting 3,5 times easier compared to standard mechanisms
- Steel gear maximises the supply of the power especially in the middle of the cut, when most help is needed
- Upper blade made from high quality hardened carbon steel
- Non stick PTFE coating on upper blade reduces friction and makes cutting and cleaning easier
- Anvil blade made from cast aluminium enables easier cutting of hard, dry wood
- Retail box: 4
- Length: 800mm
- Weight: 1220g

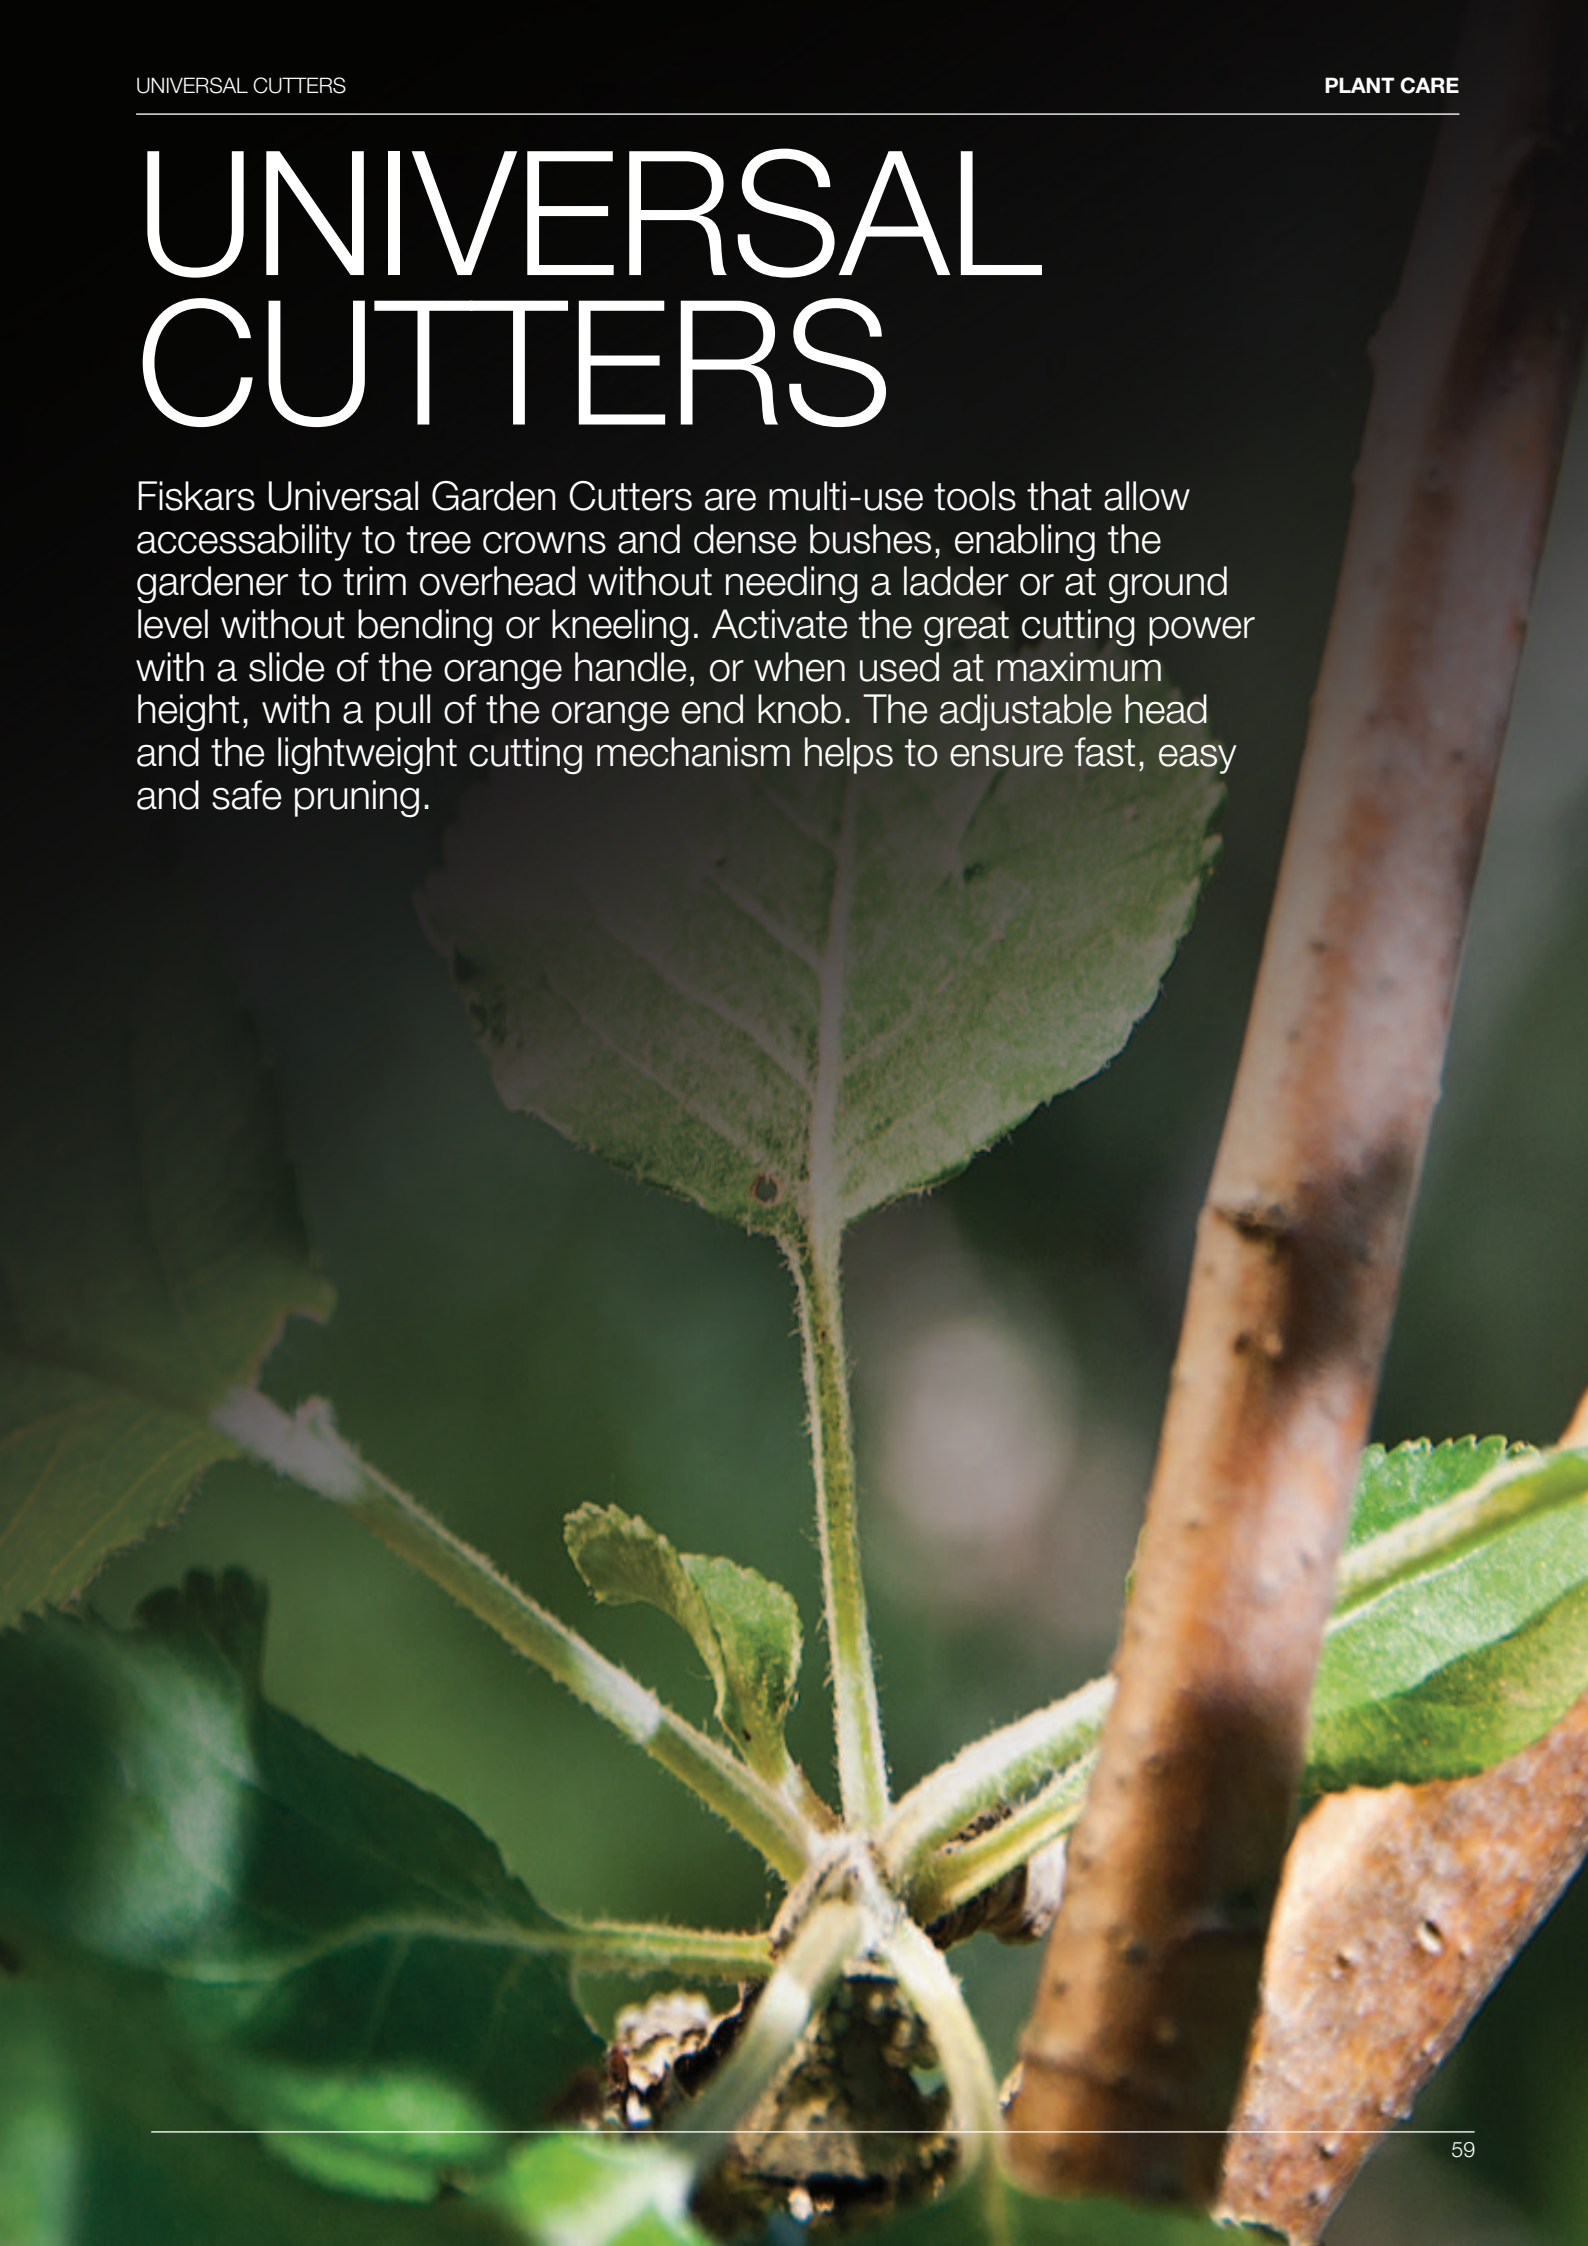
UNIVERSAL CUTTERS

Fiskars Universal Garden Cutters are multi-use tools that allow accessability to tree crowns and dense bushes, enabling the gardener to trim overhead without needing a ladder or at ground level without bending or kneeling. Activate the great cutting power with a slide of the orange handle, or when used at maximum height, with a pull of the orange end knob. The adjustable head and the lightweight cutting mechanism helps to ensure fast, easy and safe pruning.



Universal Cutters

Tree Pruner Bypass Telescopic UP86

Article No 115560

Product benefits

- Long reach shaft makes hard to reach garden tasks accessible from a safe standing position
- Shaft length adjustable from 2400mm - 4000mm enabling a maximum reach of 6 meters
- Extremely efficient PowerReel™ mechanism makes cutting 12 times easier compared to standard mechanisms
- Adjustable cutting angle up to 230°
- Bypass cutting action for cutting fresh wood
- Handy locking mechanism
- Retail box: 2
- Length: 2416mm
- Weight: 1900g

6 411502 965638

Tree Pruner Bypass Long UP84

Article No 115390

Product benefits

- Long reach shaft makes hard to reach garden tasks accessible from a safe standing position
- Cutting reach of approximately 4 meters
- Extremely efficient PowerReel™ mechanism makes cutting 12 times easier compared to standard mechanisms
- Adjustable cutting angle up to 230°
- Bypass cutting action for cutting fresh wood
- Can be used with extension pole 110460
- Retail box: 2
- Length: 2322mm
- Weight: 1200g

6 411501 963901

Tree Pruner Bypass UP82

Article No 115360

Product benefits

- Long reach shaft makes hard to reach garden tasks accessible from a safe standing position
- Cutting reach vertically about 3,5 meters
- Extremely efficient PowerReel™ mechanism makes the cutting even 12 times easier compared to standard mechanisms
- Adjustable cutting angle up to 230°
- Bypass cutting action for cutting fresh wood
- Can be used with extension pole 110460
- Retail box: 4
- Length: 1580mm
- Weight: 870g

REEL MOWER

The Fiskars Staysharp Max reel mower promote greener, healthier lawns by cutting each blade of grass cleanly with a scissor like action. This minimises moisture loss and exposure to disease. The Reel Mower lets you cut grass without noise, uncomfortable vibrations and the hazards associated with power driven rotary blades. It is also the most environmentally friendly way to cut your lawn.

StaySharp™

StaySharp™ Max Reel Mower	Article No 113880	Product benefits

- Best in class cutting performance for a superior mowing experience
- StaySharp™ cutting system cuts the grass without the blades touching so the mower is easier to push
- Hardened steel blades with precision grounded edges
- Ergonomic, height-adjustable handle with padded grip
- VersaCut™ cutting capacity settings from 2,5 cm to 10 cm
- Enables the closest side edging of any reel mower
- Retail box: 1
- Length: 1220mm
- Weight: 2350g

6411501138804

StaySharp™ Plus Parts

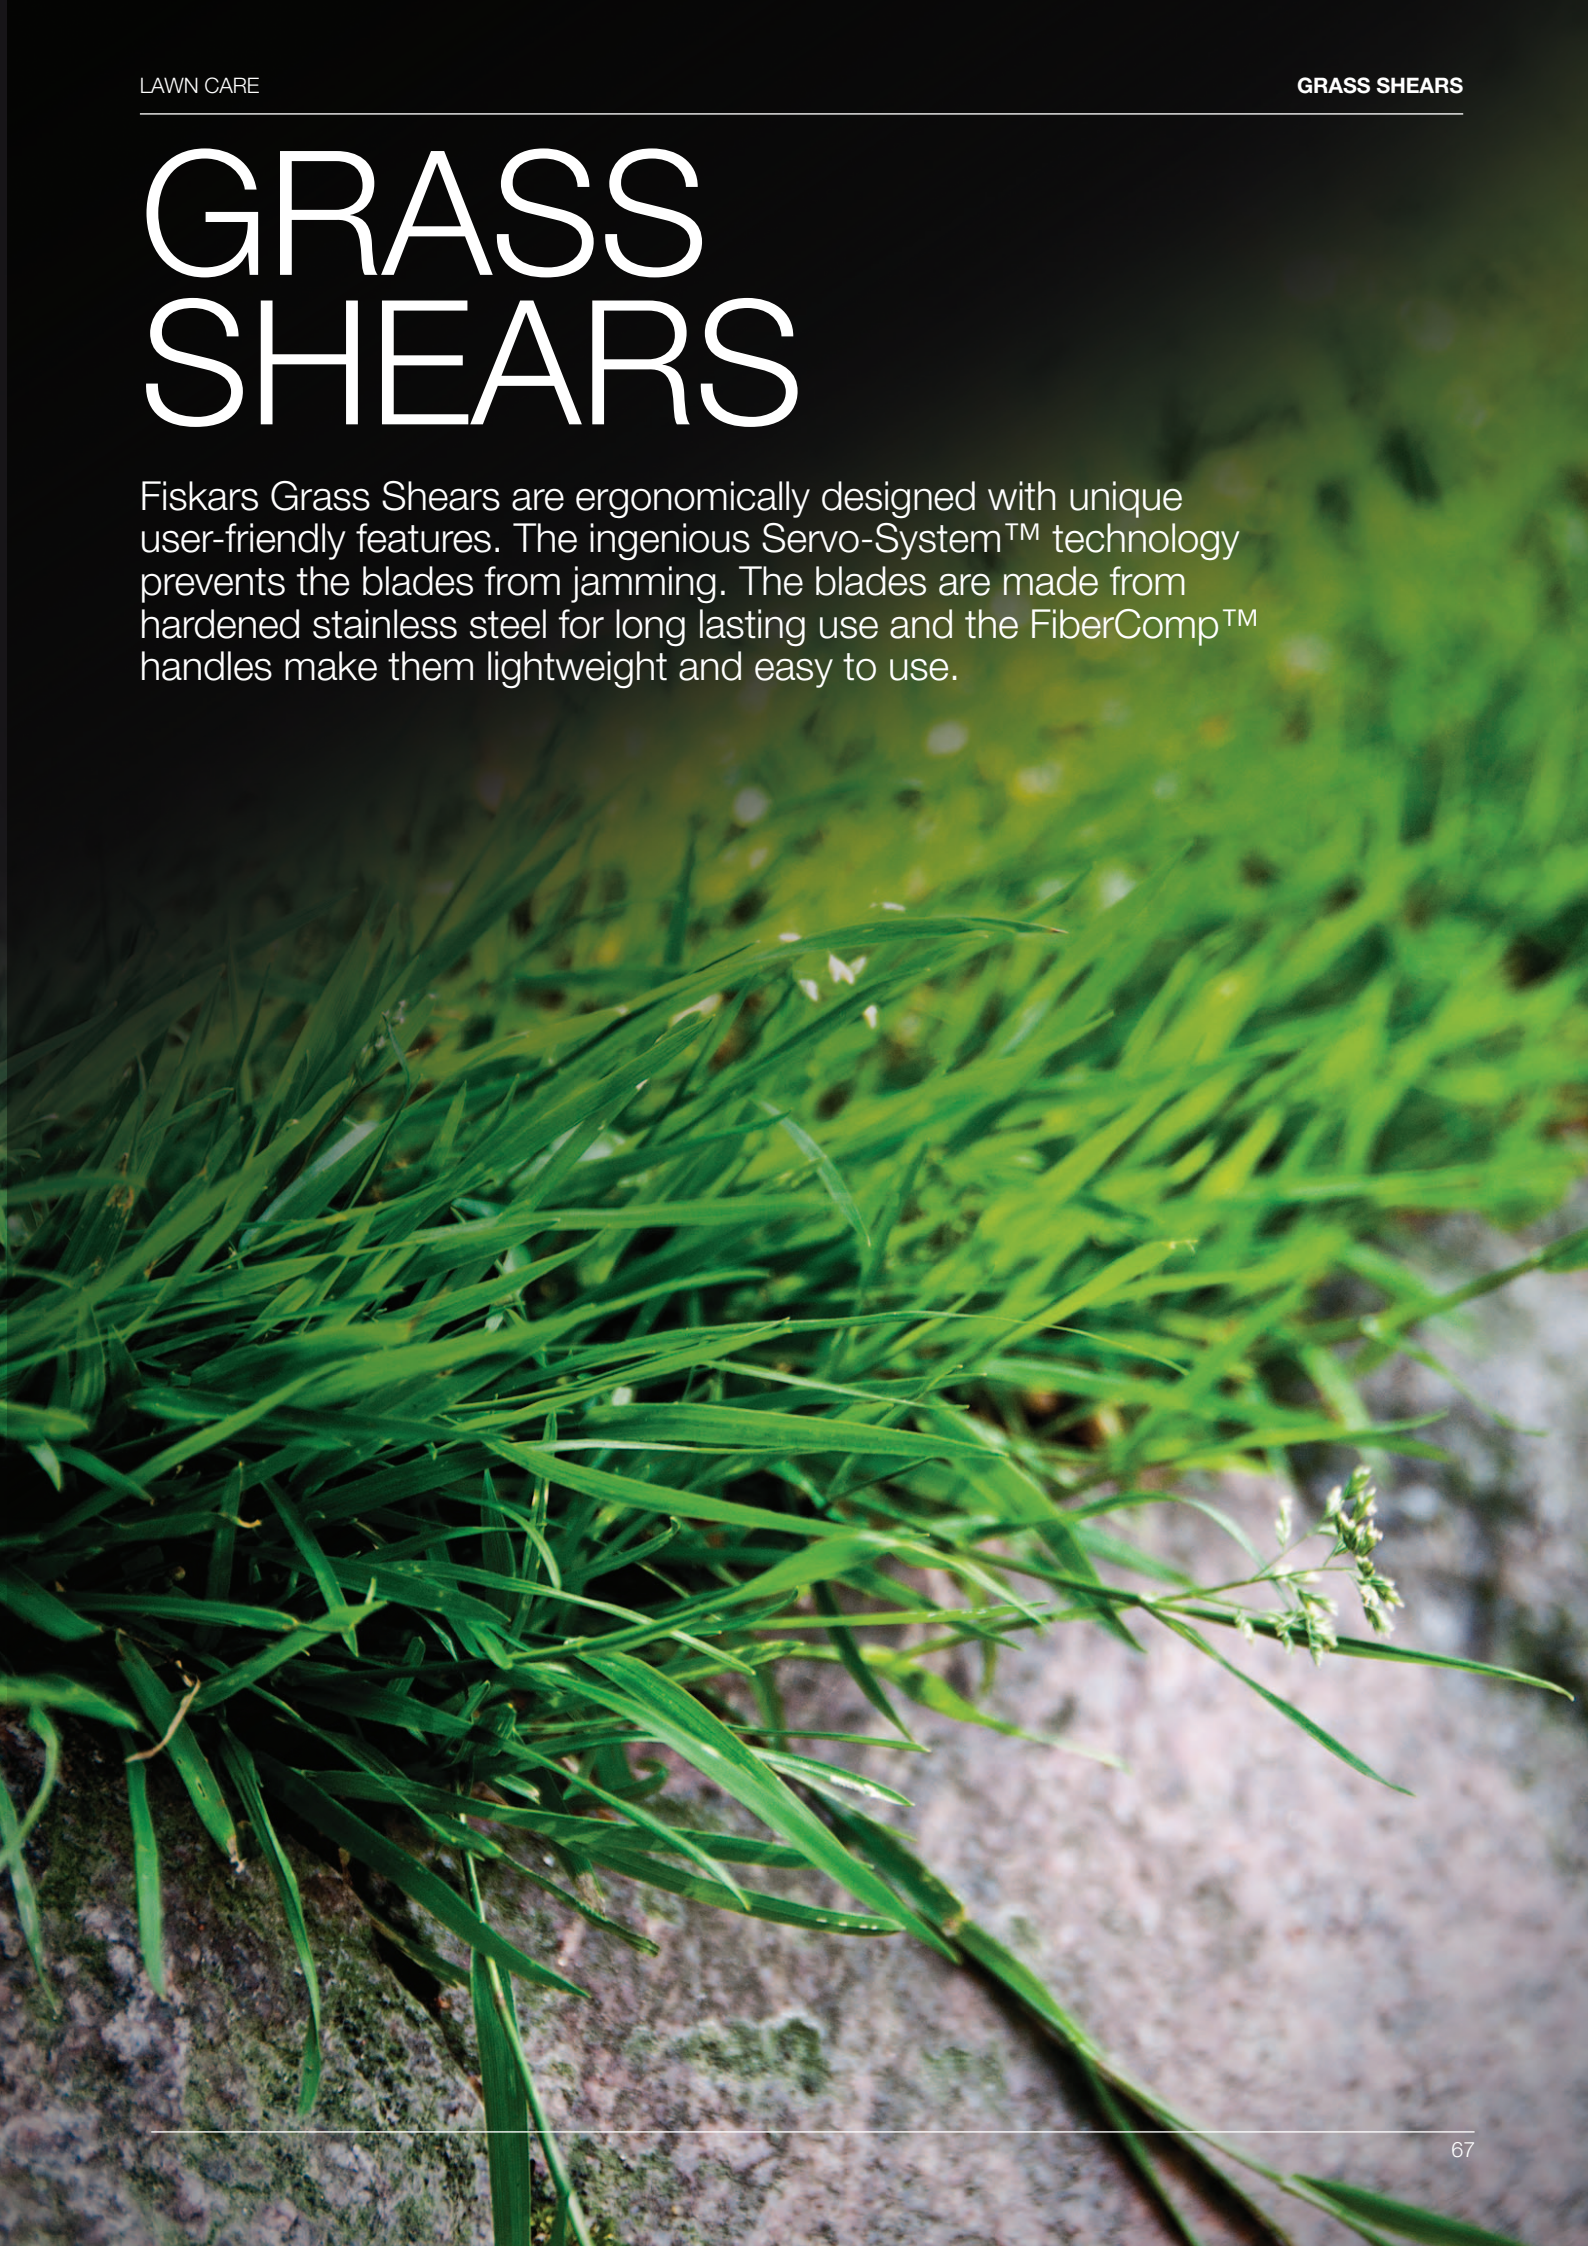
StaySharp™ Grass Catcher	Article No 113883	Product benefits

- For use with Fiskars StaySharp™ Max Mower.
- Simple to use with convenient handle for easy emptying
- Effective capacity of approx 18 litres
- UV and mildew resistant polyester screen and heavy duty steel frame for long lasting performance
- Simple tool-free assembly to mower
- Retail box: 1
- Length: 540mm
- Weight: 1400g

6411501138835

GRASS SHEARS

Fiskars Grass Shears are ergonomically designed with unique user-friendly features. The ingenious Servo-System™ technology prevents the blades from jamming. The blades are made from hardened stainless steel for long lasting use and the FiberComp™ handles make them lightweight and easy to use.



PowerLever™

PowerLever™ Grass And Hedge Shear GS53	Article No 113710	Product benefits

- For cutting grass, hedges and small bushes
- Handles made from FiberComp™ (a fiberglass reinforced polyamide) to make them extremely lightweight and strong
- Efficient PowerLever™ mechanism optimises the power output
- Cuts up to 10mm at the base of the blade
- Reaches up to 2.5m
- Allows the gardener to work in an upright position to prevent muscle strain and backache
- Cutting head adjusts up to 270°
- Retail box: 4
- Length: 899mm
- Weight: 1376g

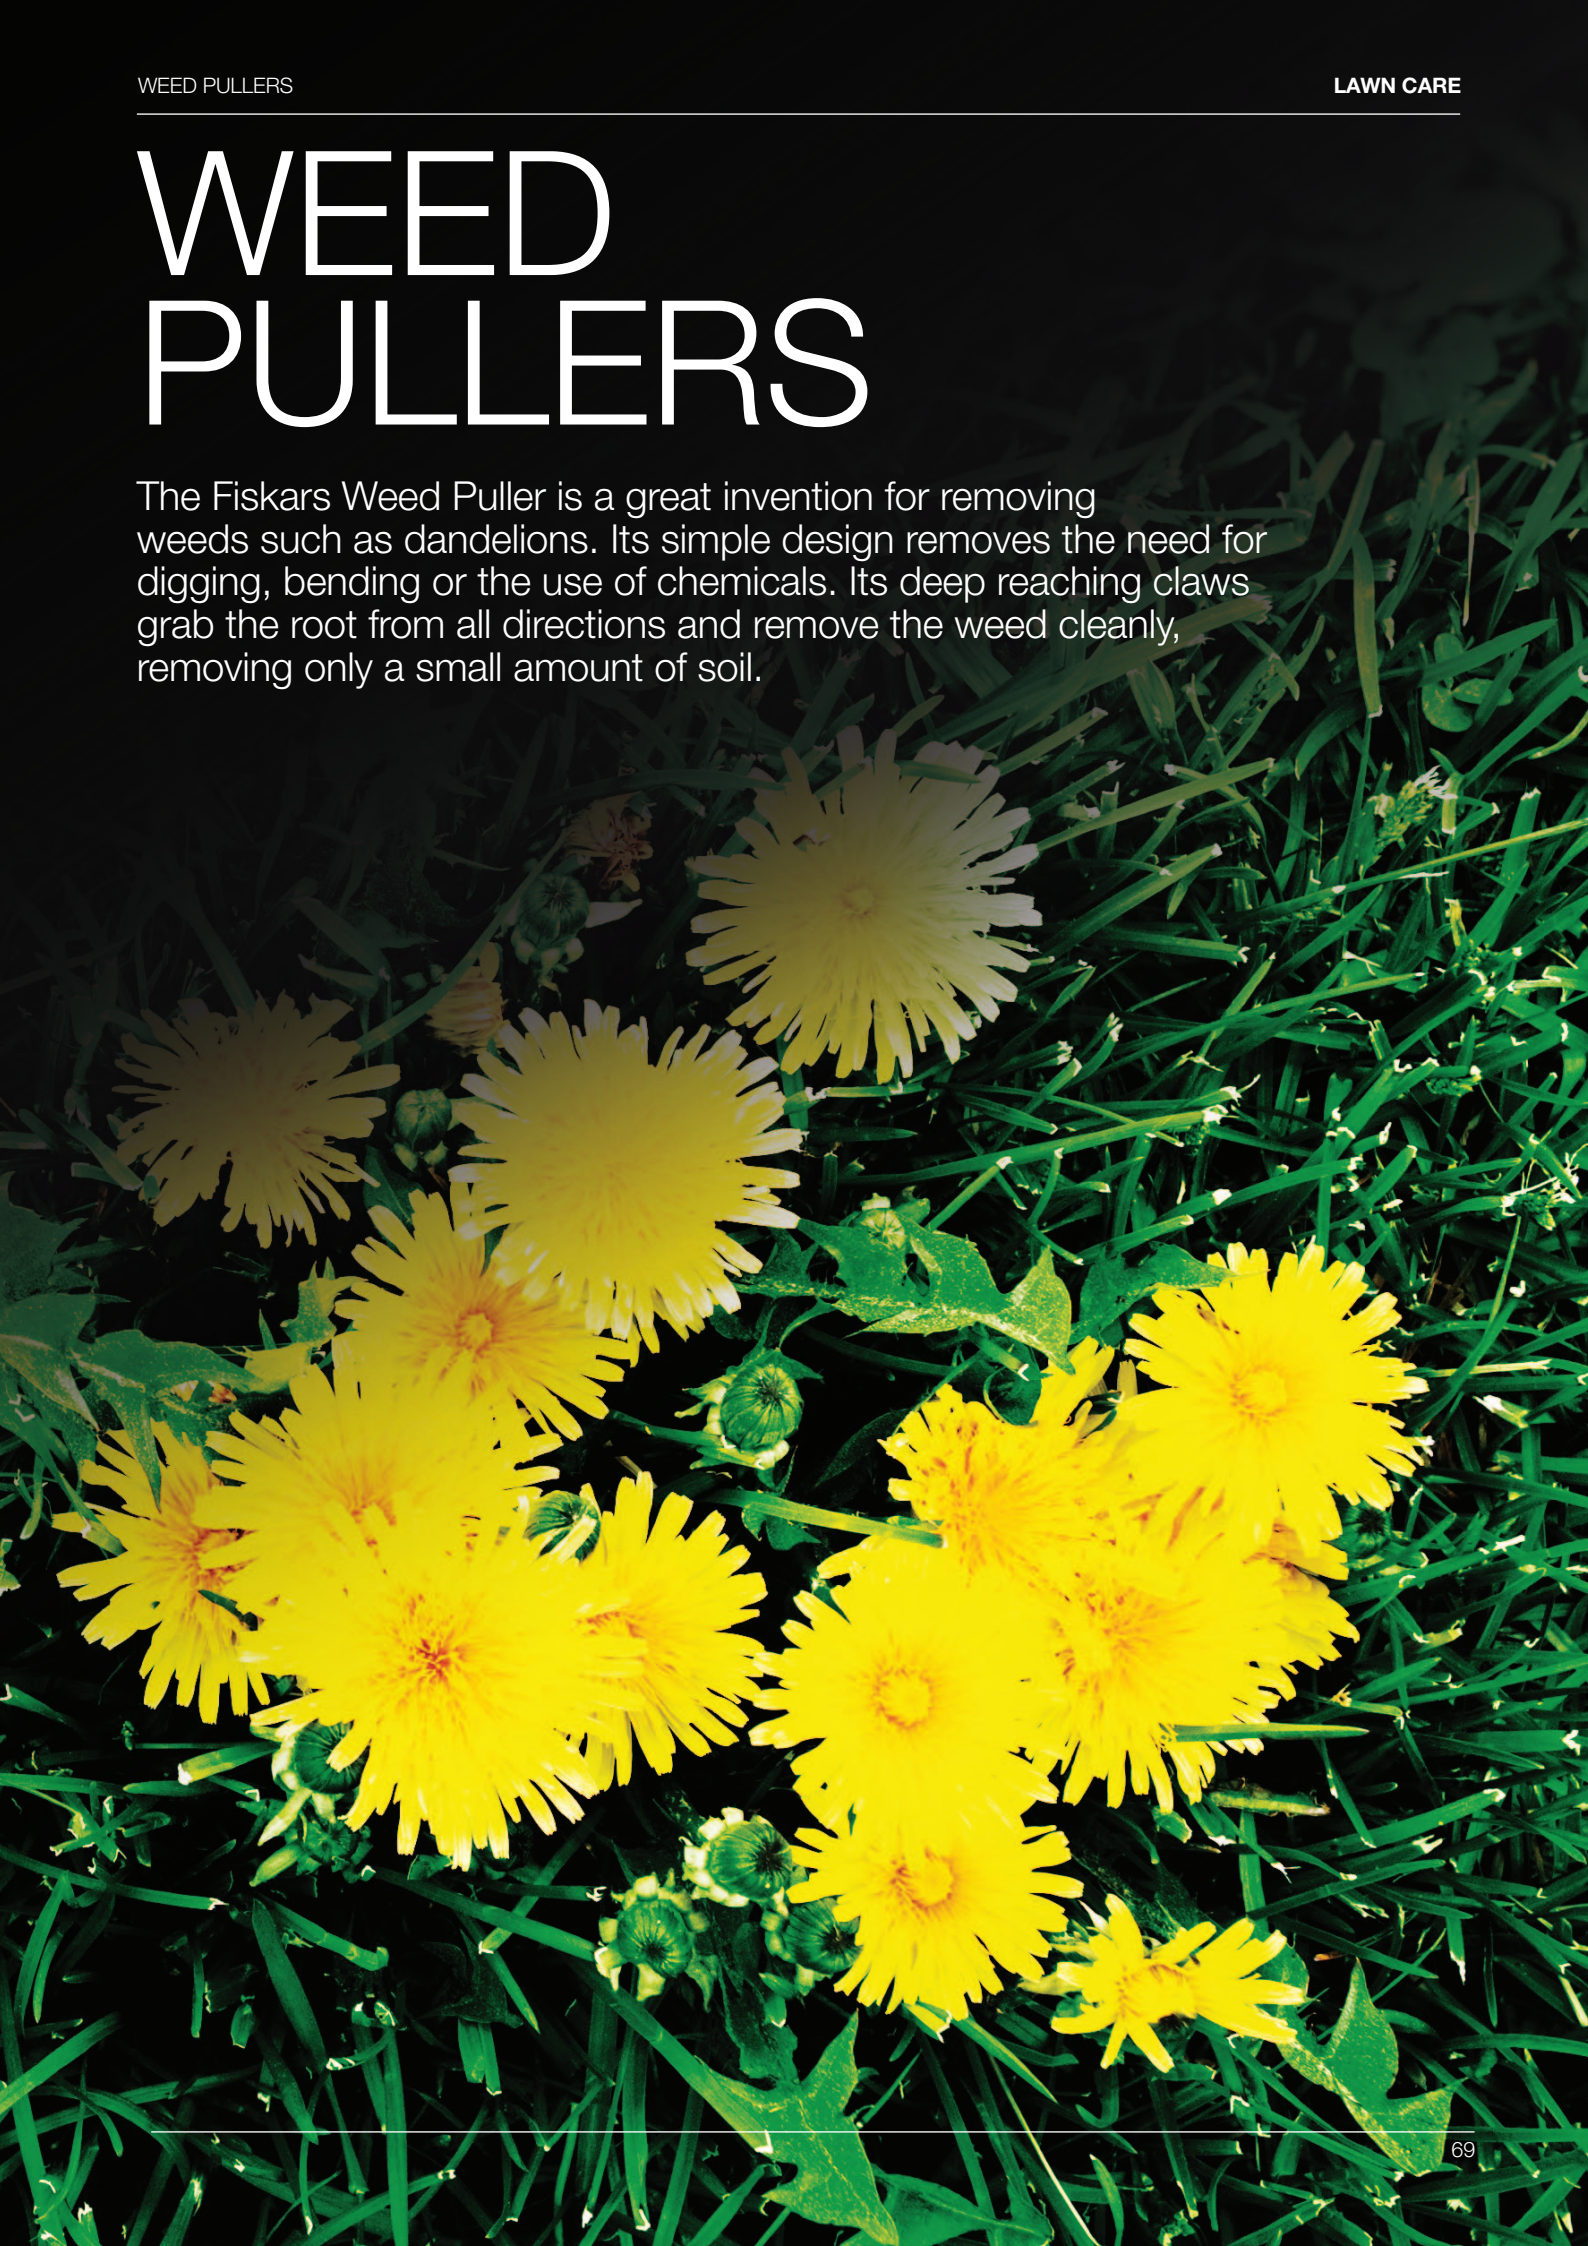
WEED PULLERS

The Fiskars Weed Puller is a great invention for removing weeds such as dandelions. Its simple design removes the need for digging, bending or the use of chemicals. Its deep reaching claws grab the root from all directions and remove the weed cleanly, removing only a small amount of soil.



Weed Puller

Weed Puller Telescopic W82	Article No 139920	Product benefits

- Four deep-reaching stainless steel claws grab the root efficiently
- Ejection system helps to release weed after pulling
- Eco-friendly weeding without the use of chemicals
- Allows the gardener to work in an upright position to prevent muscle strain and backache
- Telescopic handle can be adjusted up to 1190 mm
- Retail box: 4
- Length: 1000mm
- Weight: 1700g

RAKES

Fiskars produce a wide range of rakes for different purposes. Raking, levelling soil and preparing beds for sowing requires the right tool to give new plants the right start in the growing season. Fiskars exchangeable rake system is easy to transport and store and the durable plastic heads are rust free and easy to clean.

In-Lock

In-lock Leaf Rake L	Article No 135010	Product benefits

- Wide rake for working over larger areas
- Improved geometry of tines prevents branches and leaves from getting caught
- PBT head is durable, but flexible. Each prong has a spring action
- Retail box: 15
- Length: 228mm
- Weight: 230g

6 411503 477215

In-lock Leaf Rake M	Article No 135020	Product benefits

- 25 long, elastic and sturdy tines for the efficient raking of lawns
- PBT head is durable, but flexible. Each tine has a spring action
- Retail box: 10
- Length: 212mm
- Weight: 196g

6 411503 477116

In-lock Leaf Rake S	Article No 135030	Product benefits

- For use in difficult to access places, between plants and under bushes
- 7 long, elastic tines
- PBT head is durable, but flexible. Each tine has a spring action
- Retail box: 15
- Length: 180mm
- Weight: 46g

6 411503 476614

In-lock Universal Rake sliding wings	Article No 135050	Product benefits

- For raking long, loose grass and for working with soil
- FiberComp™ head is lightweight, does not corrode and does not damage the soil
- 12 tines equipped with drag and slide wings
- Wings easy to attach and detach
- Retail box: 10
- Length: 175mm
- Weight: 270g

Snow Shovels

Snow Light Snow Shovel	Article No 142070	Product benefits

- Aluminium shaft with ergonomic plastic coating
- Ergonomically designed handle
- Reinforced polypropylene plastic scoop prevents snow from sticking to the blades
- Aluminium scope edge
- Retail box: 3
- Length: 1310 mm
- Weight: 1050g

7 317792 359029

Snow Shovel	Article No 141000	Product benefits

- Composite shaft
- Ergonomically designed handle
- Reinforced polypropylene plastic scoop prevents snow from sticking to the blades
- Aluminium scope edge
- Retail box: 6
- Length: 1400 mm
- Weight: 1400 g

6 411503 235808

Snow and Grain Shovel	Article No 142000	Product benefits

- Birch wood shaft
- Polypropylene grip
- Blade of high quality aluminium
- Retail box: 6
- Length: 1268mm
- Weight: 1400g

6 411503 235280

Snow and Grain Shovel - Tempered	Article No 142010	Product benefits

- Birch wood shaft
- Polypropylene grip
- Blade of hardened aluminium
- Retail box: 4
- Length: 1161mm
- Weight: 2000g

6 411503 235501

Snow Light Car Shovel	Article No 141020	Product benefits

- Aluminium shaft with ergonomic plastic coating
- Ergonomically designed handle
- Hardened aluminium blade
- Retail box: 3
- Length: 715 mm
- Weight: 750 g

7 317794 310004

Ice Iron

Ice Iron	Article No 140000	Product benefits

- Excellent for scraping ice or stripping bark from trees
- Wooden shaft
- Painted blade of hardened boron steel
- Retail box: 6
- Length: 1475 mm
- Weight: 1400g

6 411503 239905

FISKARS QUIKFIT

Fiskars QuikFit™ is a range of products with interchangeable heads and handles for a variety of garden tasks from cutting to cultivating and from raking to snow care. The Fiskars QuikFit™ locking mechanism allows gardener to lock, unlock or eject easily the heads in one swift movement.

Cultivators and Hoes

QuikFit Cultivator	Article No 136511	Product benefits

- For cultivating, scarifying, aerating and breaking up soil
- Suitable for seed bed preparation and maintenance
- Blade of hardened carbon steel
- Can be used with all standard and small shafts
- Retail box: 6
- Length: 305mm
- Weight: 417g

5 905568 540423

QuikFit Cultiweeder	Article No 136512	Product benefits

- Dual tool for cultivating, scarifying, aerating and breaking up soil
- Suitable for seed bed preparation and maintenance
- Blade of hardened boron steel
- Can be used with all standard and small shafts
- Retail box: 6
- Length: 305mm
- Weight: 507g

5 905568 540416

QuikFit Grubber	Article No 136517	Product benefits

- For cultivating and aerating garden flower beds
- Blade of hardened carbon steel
- Can be used with all standard and small shafts
- Retail box: 6
- Length: 260mm
- Weight: 330g

5 905568 365170

QuikFit Push-Pull Weeder	Article No 139970	Product benefits

- Useful for weeding as it loosens the soil simply by pushing and pulling back and forth
- Hardened boron steel head
- Can be used with all standard and small shafts
- Retail box: 6
- Length: 250mm
- Weight: 358g

5 905568 540409

QuikFit Hoe	Article No 136503	Product benefits

- Efficient tool for removing weeds between rows of plants or breaking up the soil
- Blade of stainless steel
- Can be used with all standard and small shafts
- Retail box: 6
- Length: 250mm
- Weight: 254g

5 905568 540379

QuikFit Hoe 3 functions	Article No 136513	Product benefits

- For working around stems and in narrow spaces
- Blade is sharpened on 3 sides to assist cultivating at different angles
- Blade of hardened boron steel
- Can be used with all standard and small shafts
- Retail box: 6
- Length: 315mm
- Weight: 241g

5 905568 540430

QuikFit Dutch Hoe	Article No 136502	Product benefits

- Sharp, ground weeding blade for removing weeds, breaking up soil, creating seed rows or removing moss from patios
- Blade of hardened boron steel
- Can be used with all standard and small shafts
- Retail box: 6
- Length: 295mm
- Weight: 241g

5 905568 540362

QuikFit Spiker	Article No 136524	Product benefits

- Used for aerating smaller, narrower plots. Allows nutrients to penetrate the surface and helps seed, fertiliser, water, air and light to reach the roots
- Hardened steel blades
- Can be used with all standard shafts
- Retail box: 2
- Length:305mm
- Weight: 512g

6 411501 365248

Rakes

QuikFit Soil Rake 14 prongs	Article No 135511	Product benefits

- For raking, levelling or smoothing seed beds which cover a wider area
- 14 spikes of hardened carbon steel
- Can be used with all standard shafts
- Retail box: 6
- Length: 205mm
- Weight: 428g

5 905568 540300

QuikFit Soil Rake 16 prongs	Article No 135512	Product benefits

- For raking, levelling or smoothing seed beds which cover a wider area
- 16 tines of hardened carbon steel
- Can be used with all standard shafts
- Retail box: 6
- Length: 205mm
- Weight: 493g

5 905568 540317

QuikFit Universal Rake

Article No 135051

Product benefits

- For raking and clearing long loose grass and for working the soil
- Also for making planting beds by levelling the ground and sand and packing down the soil
- The essential tool for finishing the surface before sowing seeds
- 12 FiberComp™ tines designed at a specific angle to help with ergonomic posture
- Can be used with all standard shafts
- Retail box: 6
- Length:152mm
- Weight: 260g

6 411501 350510

QuikFit Rose Rake

Article No 135501

Product benefits

- Unique head shape allows the gardener to work between plants and stems without damaging the plants
- Ideal for narrow bed layouts
- 10 teeth of hardened boron steel
- Can be used with all standard shafts
- Retail box: 6
- Length: 225mm
- Weight: 233g

5 905568 540355

QuikFit Leaf Rake metal

Article No 135201

Product benefits

- For removing loose moss and grass cuttings from the lawn
- 22 flexible steel prongs
- Can be used with all standard shafts
- Retail box: 6
- Length: 470mm
- Weight: 445g

6 411501 352019

QuikFit Leaf Rake L

Article No 135013

Product benefits

- Wide rake for gathering fallen leaves and grass cuttings
- Tines work in a pulling direction providing more comfort with less effort
- 25 soft and flexible tines of high quality PBT plastic that will withstand bending
- Can be used with all standard shafts
- Retail box: 6
- Length: 320mm
- Weight: 290g

6 411501 350138

QuikFit Gather Rake

Article No 135514

Product benefits

- Wide rake for gathering leaves and cutting waste from lawn areas
- Hardened carbon steel head
- Can be used with all standard shafts
- Retail box: 2
- Length: 570mm
- Weight:1017g

5 905568 540331

QuikFit Leaf Rake S	Article No 135551	Product benefits

- Convenient small leaf rake for clearing around narrow beds and borders
- Tines work in a pulling direction providing more comfort with less effort
- 11 soft and flexible tines of high quality PBT plastic that will withstand bending
- Can be used with all standard shafts
- Retail box: 6
- Length: 310mm
- Weight: 160g

6 411501 355515

QuikFit Aerator Rake	Article No 135513	Product benefits

- For removing moss and thatch from lawn areas
- Hardened carbon steel head
- Can be used with all standard shafts
- Retail box: 2
- Length: 270mm
- Weight: 961g

5 905568 540324

Edgers and Knifes

QuikFit Patio Knife	Article No 136521	Product benefits

- Ideal tool for removing grass, moss and weeds from between slabs, block paving, wall corners and steps
- Blade of hardened boron steel
- Can be used with all standard and small shafts
- Retail box: 6
- Length: 250mm
- Weight: 136g

5 905568 540393

QuikFit Lawn Edger	Article No 136526	Product benefits

- For clearing the space between the lawn and hard surfaces by stepping on the blade and driving it deep into the lawn
- For edging the borders
- Hardened boron steel head with flat top
- Can be used with all standard and small shafts
- Retail box: 6
- Length: 260mm
- Weight: 238g

5 905568 540454

Nursery Tools

QuikFit Weed Extractor

Article No 137522

Product benefits

- For removing weeds such as dandelions and burdocks
- Ideal for narrow bed layouts
- Boron steel head
- Can be used with small and medium shafts
- Retail box: 6
- Length: 328mm
- Weight: 225g

5 905568 375223

QuikFit Flower Rake

Article No 135552

NEW

Product benefits

- Durable FiberComp™ frame and 7 steel tines construction
- 13 cm working width - ideal for nursery spaces and narrow plant beds
- Can be used with small and medium shafts
- Retail box: 6
- Length: 384mm
- Weight: 210g

6 411501 355522

QuikFit Weed Fork

Article No 137552

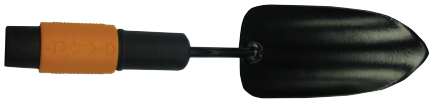
Product benefits

- For transplanting, cultivating and weeding
- Boron steel head
- Can be used with small and medium shafts
- Retail box: 6
- Length: 273mm
- Weight: 215g

5 905568 375520

QuikFit Trowel

Article No 137512



Product benefits

- For planting and transplanting
- Boron steel head
- Can be used with small and medium shafts
- Retail box: 6
- Length: 318mm
- Weight: 260g

5 905568 375124

QuikFit Cultivator angled

Article No 136515

Product benefits

- For loosening and aerating plant beds to optimise nutrient distribution
- Tool design protects plants roots
- Carbon steel head
- Can be used with small and medium shafts
- Retail box: 6
- Length: 305mm
- Weight: 235g

5 905568 365156

QuikFit Double Scraper Hoe	Article No 137562	Product benefits

- Versatile use on patios and for removing grass, moss and weeds from between tiles and slabs
- Can also be used to cultivate plant beds
- Boron steel blades with carbon steel thong
- Can be used with small and medium shafts
- Retail box: 6
- Length: 187mm
- Weight: 220g

5 905568 375629

QuikFit Double Hoe	Article No 137572	Product benefits

- Versatile use with dual functionality
- For breaking up soil, cultivating plant beds and weeding
- Boron steel blades with carbon steel thong
- Can be used with small and medium shafts
- Retail box: 6
- Length: 187mm
- Weight: 205g

5 905568 375728

Yard Cleaning

QuikFit Gutter Cleaner	Article No 135542	Product benefits

NEW

- Combination of brush and scraper offers full complement gutter cleaning capabilities
- Adjustable angle ensures optimal positioning of tool safely from the ground
- For use with telescopic shafts
- Retail box: 6
- Length: 310mm
- Weight: 330g

5 905568 355423

QuikFit Yard Broom	Article No 135532	Product benefits

NEW

- All purpose yard broom
- Featuring Fiskars PowerClean™ combing soft and hard bristles for efficient sweeping
- Can be used with all standard shafts
- Retail box: 6
- Length: 260mm
- Weight: 340g

5 905568 355324

QuikFit Patio Broom	Article No 135533	Product benefits

NEW

- For sweeping smooth surfaces like patios, wooden decks and polished concrete floors
- Wide brush head and soft bristles ensures fast efficient sweeping
- Can be used with all standard shafts
- Retail box: 6
- Length: 380mm
- Weight: 370g

5 905568 355331

QuikFit Sweeping Broom	Article No 135534	Product benefits

NEW

- A modern take of the traditional sweeping broom
- Robust construction and long bristles ideal for coarser debris, leaves etc
- Can be used with all standard shafts
- Retail box: 6
- Length: 260mm
- Weight: 375g

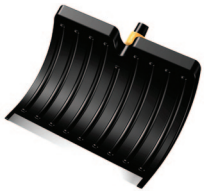
5 905568 355348

QuikFit Paving Brush	Article No 135522	Product benefits

- For removing moss and weeds from between paving slabs
- Steel bristles to scrub paving and slabs
- Additional front blade to remove tight moss and dirt
- Lightweight FiberComp™ construction which is more durable and resistant to moisture
- Retail box: 6
- Length: 185mm
- Weight: 160 g

5 905568 355225

QuikFit Snow Pusher	Article No 143210	Product benefits



- Ideal for clearing snow from steps and patios
- Scoop of PP plastic with aluminium edge
- Retail box: 2
- Length: 320mm
- Weight: 510g

6 411501 432100

Tree Care

QuikFit Tree Cutter	Article No 136525	Product benefits

NEW

- Enhanced cutting power with PowerReel mechanism
- Lever and reel bring x12 cutting power compared to standard mechanisms
- Cutting from in front of the branch
- Cutting head angle can be adjusted to a second position of 26° angle without having to lower the product
- Two-hand hold brings stability
- No external ropes on the cutting head
- Retail box:6
- Length:400 mm
- Weight: 480 g

6 411501 365255

QuikFit Curved Saw	Article No 136527	Product benefits

- Pull saw with branch hook
- Designed for reaching tasks - suitable for use with QuikFit™ Telescopic Shafts 136032 and 136042
- Hook end blade ensures non-slip steadiness while the lower cutting knife ensures a clean and precise cut from below
- FiberComp™ slider and adaptor
- Hardened steel blade. Length 360mm
- Steel cutting knife
- Retail box: 6
- Length: 550mm
- Weight: 310g

5 905568 365279

QuikFit Straight Saw	Article No 136528	Product benefits

- For sawing tasks in the garden
- Specifically designed for use with the 30cm Handle 136012
- FiberComp™ slider and adaptor
- Hardened steel blade. Length 345mm
- Retail box: 6
- Length: 520mm
- Weight: 260g

5 905568 365286

QuikFit Fruit Picker	Article No 136950	Product benefits

- Broad opening, optimal design which directs the fruit to the end of the tips for easy pulling from the branch
- Cotton bag, which can be removed for washing
- FiberComp™ lightweight design for added durability
- Can be used with regular or telescopic shafts
- Retail box: 6
- Length: 320mm
- Weight: 250g

5 905568 369505

Shafts

QuikFit Telescopic Shaft L	Article No 136032	Product benefits

- Especially designed for hard to reach tasks in the garden with a reach of up to 6m
- A unique automatic lock makes the tool ready to use in seconds
- Dual locking system for maximum safety
- Lightweight aluminium
- Retail box: 4
- Length: 2200 - 4000mm
- Weight: 1470g

5 905568 360328

QuikFit Telescopic Shaft M	Article No 136042	Product benefits

- Especially designed for hard to reach tasks in the garden with a reach of up to 4m
- A unique automatic lock makes the tool ready to use in seconds
- Dual locking system for maximum safety
- Lightweight aluminium
- Fits conveniently into most cars
- Retail box: 6
- Length: 1400 - 2400mm
- Weight: 1000g

5 905568 360427

QuikFit Shaft L	Article No 136001	Product benefits

- Tear drop profile shape hardened aluminium shaft with SoftGrip™ handle for optimum comfort
- Hanging hole for easy storage
- Shaft for all-around use in garden
- A unique automatic lock makes the tool ready for use in seconds
- Retail box: 6
- Length: 1560mm
- Weight: 475g

5 905568 540461

QuikFit Shaft M	Article No 136022	Product benefits

- Medium-length shaft which can be used with nursery tools, cultivators and hoes
- Tear drop profile hardened aluminium shaft with SoftGrip™ handle for optimum comfort
- A unique automatic lock makes the tool ready for use in seconds
- Hanging hole for easy storage
- Retail box: 6
- Length: 845mm
- Weight: 290g

5 905568 360229

QuikFit Handle S	Article No 136012	Product benefits

- Small handle ideal for use with nursery tools
- Aluminium tear drop shaped frame with FiberComp™ and a SoftGrip™ handle for optimum comfort
- A unique automatic lock makes the tool ready for use in seconds
- Hanging hole for easy storage
- Retail box: 6
- Length: 305mm
- Weight: 165g

5 905568 360120

Adaptor

QuikFit Universal Adapter	Article No 130000	Product benefits

- For connecting a variety of interchangable heads produced by other manufacturers
- Lightweight FiberComp™ construction
- Retail box: 6
- Length: 171mm
- Weight: 71g

6 411501 300003

reddot design award
winner 2010

Fiskars QuikFit™ Locking system - winner of the Red Dot Award: Product Design 2010.
The QuikFit™ mechanism ensures effortless change of heads for rakes, cultivators, hoes, weeders, saws etc. The heads attach to the shaft and the device is immediately ready for your use.

CHILDREN'S TOOLS

Being together with your children in the garden, whether for play or working together to raise plants, rake leaves or to make a clean sweep is a simple pleasure that benefits the whole family. At Fiskars we have developed tools that offer both avenues for exploration, whether a box set of unique tools for the youngest to participate, all the way through to fully functioning stick tools for older children keen to help out with real garden work.

Children's Tools

My First Fiskars® Display

Article No 138210

Product benefits

Compact dispay solution - instantly ready for sales. No assembly work or filling of tools required. Effective size of a half EUR-pallet e.g. 600mmx800mm. Dispay delivered with product brochures and try out samples for small garden tools.

NEW

Content:

Article No 138220

Product benefits

NEW

- Capacity: 2 litres
- Retail box: 8
- Length: 330mm
- Weight: 128g

6 411501 382207

EDUCATION

CHOPPING VS. SPLITTING

Chopping axe – The Universal Chopping Axe's thin, wide edge ensures a clean, easy cut in fresh, resinous wood, like spruce or pine.

Splitting axe – The Splitting Axe features a unique cutting edge that easily slices into the wood, which the thick axe blade then pushes apart.

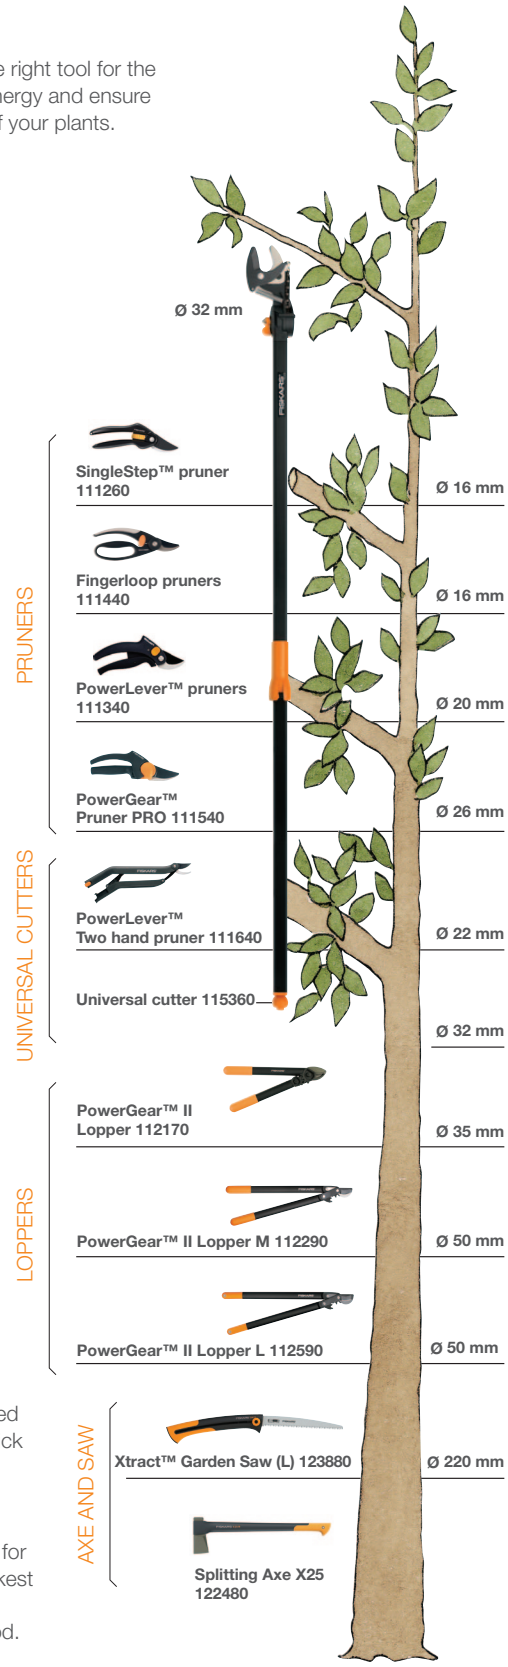
ANVIL VS. BYPASS

Bypass: Both blade and counter blade press into the wood to make a clean cut with less compression damage (cutting blade bypasses counter blade in a scissors-like action). Possible to cut close to the stem. Best suitable for fresh wood.

Anvil: Upper blade is forced through the wood with greater pressure as the anvil blade supports the branch and spreads the pressure until the cut is complete. Best suitable for dry or dead wood.

WHICH TOOL FOR WHICH TASK

By selecting the right tool for the job you save energy and ensure the wellbeing of your plants.



PACKAGING

Product Names

Fiskars products are named using letters and numbers. The letter refers to the product and the number represents which of our Supreme, Dynamic and Essential range it belongs to.

Letter
P – Pruner
L – Lopper
W – Weeder
S – Scissors

Number
Essential: 01 - 39
Dynamic: 40 - 99
Supreme: 100+

P26

Supreme Dynamic Essential

All Fiskars products are ranked as either Supreme, Dynamic or Essential. This is represented on our packaging numerically and through colour coding in the top right hand corner.

Supreme P100 | Dynamic P54 | Essential P26

Relevant Package Images

The package visual illustrates the context of the product's usage to help you select your new tool.

Product Technology

This is where we list our award winning technology. Fiskars garden tools have long been recognised for their superior quality, design and innovation.

PowerGear™
PowerStep™
PowerReel™

Pictograms

Product benefits and features are visually described using icons.

The icons fall into 3 categories:
1. Usage – what the product should be used for
2. Material – what the product is made of
3. Features – what defining features the product has

FISKARS®
Quality
Since 1649

Made in Finland

Founded in the small village of Fiskars, Finland in 1649, the company has grown into a large multinational corporation, celebrated for a history of products accommodating the strict Finnish standards for quality and design. Following its tradition to drive innovation of tools that reduce the effort, fatigue and strains so often associated with gardening, Fiskars ergonomic, high performance cutting and landscaping tools are designed to do the hard work, so you don't have to!
